There was a good deal of sickness during the next week, but the patient's condition was not appreciably altered. On Aug. 5th she was worse. There was more abdominal pain and profuse diarrhœa, and some delirium during the night. The pain subsided on the following day, but the diarrhœa persisted with varying intensity until death, which occurred on Aug. 12th. The temperature was subnormal, except on two occasions when it reached 100°, and during the last four days when the evening temperature was raised about one degree. The bowels acted on an average three times a day. The urine never contained albumen.

Necropsy, twenty-four hours after death.—Body greatly emaciated. Thoracic viscera healthy. No naked-eye lesions of kidneys or spleen. There was considerable gaseous distension of the intestines. In the lower three feet of the ileum there was well-marked thickening of the wall of the gut, and the mucous membrane of this portion was much swollen and shaggy. The patches of Peyer in this region were unduly swollen, and in the two lowest were several small, clean-cut, circular ulcers, with smooth bases. Besides these, there were several large, irregularly-shaped ulcers, with sharp edges and smooth bases, exposing the muscular coat; and over the last ten inches of the ileum the swollen mucous membrane was crowded with small, crater-like ulcers, both on and between the rugæ. In the large intestine the ulceration was much more general and extensive. From the valve to the splenic flexure the greater portion of the mucous membrane had entirely disappeared, leaving only a number of islets of varying shape and size. Some of the largest of these were undermined for a considerable way, so as to form bridges of swollen mucous membrane over collections of pus and shreddy caseous débris. In the intervening smooth areas the thickened muscular coat was laid bare. The serous surface of the gut was everywhere of normal aspect and free from adhesions. There was no contraction at any point. In the descending colon and sigmoid flexure the ulceration was rather less extensive, but of the same character. In the rectum the ulcers were still more scattered, and with one or two exceptions both smaller and shallower than elsewhere, and apparently of more recent date. Dr. Pasteur is unable to make any exact statement as to the colour and general appearance of the intestine at the time of death, as the specimen only came under his observation after being some time in spirit, and very brief notes were taken at the necropsy.

CASE 3 will be found described at length in the Middlesex Hospital Reports, 1885, p. 45. The patient was a woman, aged forty-five. She enjoyed good health until twelve months before her death, when she began to suffer from diarrhœa and tenesmus, which continued until death.

On admission there was severe diarrhœa with intensely fetid stools, occasionally containing blood, and "fleshy masses." She improved temporarily under large injections

Digitized by Google

of nitrate of silver (twenty grains to the ounce), but eventually died of asthenia. The small intestine was not affected, but the large gut from beginning to end presented most typically the appearances found in dysentery. The other organs were practically healthy.

Remarks by Dr. PASTEUR.—The rarity of cases of non-imported sporadic dysentery is, I think, generally acknowledged. In support of this I may state that I have failed to find a single case recorded as such in the Transactions of the Pathological Society. And yet, in view of the clinical and pathological aspects of each of these cases, there cannot, I think, be any doubt that they are well-marked instances of the disease. Of the predisposing and determining causes I could get no information. The affection of the ileum in Case 2 is remarkable, and of uncommon occurrence even in the tropical variety of the disease. It accords strikingly with the description of it given by Hilton Fagge. Looking at the advanced stage of the affection in all three cases it is not surprising that treatment should have proved entirely unavailing. The absence of the characteristic fetor of the stools in the first two cases is worthy of note, and, judging by the writings of some authors on tropical dysentery, would have been sufficient to exclude the diagnosis.

BATH EASTERN DISPENSARY.

MALIGNANT DISEASE OF THE ŒSOPHAGUS; RELIEF BY GASTROSTOMY; DEATH TWENTY-EIGHT DAYS AFTER THE STOMACH WAS OPENED.

(Under the care of Mr. R. J. H. SCOTT.)

MARY ANN Z——, aged sixty-one. Has a consumptive family history. Had rheumatic fever sixteen years ago (?). About a year previously to admission she began to find difficulty in swallowing large pieces of food (no difficulty with fluids); this gradually increased until five months ago, when she had a fall (owing, she says to weakness), since which time the dysphagia has rapidly increased, and she has become much weaker. Five months ago pain commenced behind the larynx and on the left side of the neck, which also passed down the left arm, and was so great that she often lost sleep at night.

About April 14th the patient was in the following condition:—There was a tumour behind the larynx pressing it forwards; it was hard, firmly attached to the tissues around, and appeared as an oval swelling on each side of the larynx, about two inches in size from above downwards, and five inches across. There was pain on palpating the tumour, most marked on the left side, on which side also the cervical glands were much enlarged and tender. She was totally unable to swallow any solids, and with the greatest difficulty any fluids; usually on attempting to swallow fluids they were immediately ejected together with blood-stained mucus. She was frequently attacked with fits of coughing which ended in her expectorating mucus tinged with blood, and at times purulent sputa with a most offensive odour. She complained of a great craving for food, and was very thirsty. Passing urine also gave her great pain, the amount being only a few ounces in twenty-four hours, highly concentrated. The bowels were confined; the skin of her legs and arms was much shrivelled, and was red over bony prominences such as the malleoli, with a tendency to form bed-sores. The operation of gastrostomy, and the benefit she was likely to receive from it, having been explained to her, she consented to it being performed.

On April 16th, being under the influence of bichloride of methylene, and the skin of the abdomen having been washed with carbolic lotion, an incision was made about two inches and a half in length, parallel with, and about one inch below, the left costal cartilages. One or two small vessels were secured with catgut ligatures before the abdominal cavity was opened. The left lobe of the liver presented itself at the opening into the peritoneum; on pushing this to the right the lower margin of the stomach could just be seen moving with respiration under the left costal cartilages; this was seized with a pair of artery forceps and drawn carefully into the wound; a carbolised silk suture was then passed through its walls, by which it could be held in position in the wound. The stomach was next fixed to the abdominal wall by a double row of carbolised silk sutures care being taken only to transfix the muscular and peritoneal coats of the viscus. After eight sutures had fixed the stomach to the parietes so as to completely close the peritoneal opening, the part of the stomach exposed in the wound was then attached to the edges of the wound with small carbolised silk sutures. The wound was dressed with antiseptic gauze and salicylic wool. No spray was used, otherwise the operation was done antiseptically. In suturing the stomach to the abdominal wall the incised margins of the parietal peritoneum were brought well forward into the wound, so that as broad a surface as possible might be kept in contact with the visceral peritoneum. The dressing was not removed for five days, when the stomach was opened. During this time she was fed with nutrient suppositories twice a day. She expressed herself as feeling better soon after the feeding by suppositories commenced. No pain since operation. On April 21st the dressings were removed and the wound washed out with carbolic lotion; it had apparently quite healed. A narrow-bladed knife was passed into the stomach by the side of the silk ligature which had been used to bring the viscus into position whilst being sutured to the abdominal parietes; this caused the patient no pain. A No. 6 gum-elastic English catheter was now introduced by the side of the blade of the knife, which was withdrawn when the catheter was felt to have entered the stomach. Suction was made at the end of the catheter, with a sufficiently disagreeable result to prove that the tube was in the gastric cavity. A funnel and piece of flexible tubing was fastened to the end of the catheter, and six ounces of peptonised milk (warm) was gently poured in. The catheter was cut short to within three inches of the wound with a piece of salicylic wool in its open end, and the whole covered with salicylic wool and strapping. Nutrient suppositories stopped.

On the next day she was fed twice in the same manner, and with the same food. She expressed herself as feeling better than she had done for a long time, and that she had been able to pass more urine, which had given her great relief. She was allowed to sip a little Liebig beef and malt wine.

April 23rd.—Sutures removed. There is some excoriation around the tube, which is loose. A No. 8 gum-elastic catheter was now substituted for the No. 6 without any difficulty. She now takes ten ounces of peptonised milk twice a day. Salicylic wool packed around the catheter.

25th.—The gastric juice oozes by the side of the catheter, and keeps the surrounding skin excoriated. An elastic flexible tube, rather larger than a No. 12 English catheter, was now substituted for the No. 8, and an egg was beaten up in ordinary milk, about twelve ounces being slowly introduced twice a day. Patient says she feels much better. Urine gives no pain on passing, and is much increased in quantity. Has had a natural motion; says her skin feels much more comfortable, as it felt shrivelled before. The excoriated skin was painted over with a solution of nitrate of silver.

28th.—The skin around the wound now looks quite healthy. She is able to feed herself through the tube, which she takes out, cleans, and reintroduces, and she takes thickened beef-tea or mutton-broth at one meal, and milk and egg at another. As she complained of indigestion, she now adds a teaspoonful of liquor pepticus to each meal, which gives her great relief. Washes her mouth with cold tea.

May 6th.—Continues to feed herself very comfortably. The expectoration has increased and the tumour in the neck has grown larger. Nothing passes through the stricture. The glands in the left side of the neck are increasing in size and becoming more painful. Complains of great pain down the left arm, which she is now hardly able to use.

12th.—Pain in the arm and neck increasing. Still takes plenty of nourishment. Says the operation has given her immense relief from craving hunger and insatiable thirst; at the same time she is gradually becoming weaker.

The patient died on May 19th, apparently of exhaustion.

Remarks by Mr. SCOTT.—Though this patient only lived twenty-eight days after the stomach was opened, yet I cannot help considering that the operation was successful, gastrostomy being an operation the object of which is to relieve hunger and thirst, and as far as possible to prolong life, her condition before the operation being intense hunger, great thirst, and concentrated urine; all these were relieved, especially her pain in passing urine, which was no slight addition to her other troubles. There is no doubt that gastrostomy should be performed as soon as the patient is unable to swallow solids, but it is very difficult to induce patients to

Digitized by Google

consent to its being performed so early as this. In the present case the patient had attended at the hospital out-patient department quite three weeks before, and I had endeavoured to persuade her to have the operation done, but she positively refused till later on, when she was able to take no nourishment at all. In the *British Medical Journal* of May 21st Mr. Golding Bird of Guy's Hospital reports a case in which he tried immediate feeding, but the patient died six hours after the operation. I cannot help feeling that if the patient is in such an extremely exhausted condition gastrostomy will be of little use; and if of little use, will do harm by bringing discredit on the operation. The operation is not a painful one, and therefore, if we can only induce patients to consider that by having it done earlier they will prolong life and lessen some of the terrors of the kind of death they will ultimately have to pass through, we shall, I think, do our duty to our patients and give the operation its due value in surgery. The strength of the patient may be fairly well kept up by nutrient suppositories during the few days that the stomach remains unopened, and these may be assisted by injections of tepid water, about four ounces in quantity, three or four times in twenty-four hours; the water appears to become absorbed, and gives relief to the intense thirst often occurring in these cases. Mr. Charters Symonds, in the *Journal* of April 23rd, brings forward four cases of the treatment of epitheliomatous stricture of the œsophagus by tubage or permanent catheterism. Three of his cases died finally of ulceration extending to neighbouring parts—i.e., the pleura and lung, the trachea, and the retro-pharyngeal or œsophageal tissues. I think that the passage of a tube, however soft, through a cancerous ulcerating growth must tend to hasten the ulcerating process; whereas, on the other hand, gastrostomy, though it does not stop the growth of the tumour (excepting by preventing the irritation of attempting to swallow food and fluid), does not, in any way that I can see, hasten the end.

OF
INTRODUCTORY LECTURES, ETC.,
DELIVERED AT
MEDICAL SCHOOLS OF LONDON AND THE PROVINCES
AT THE
Opening of the Session 1887-88.

ST. GEORGE'S HOSPITAL.

INTRODUCTORY LECTURE BY MR. C. T. DENT, F.R.C.S.

AFTER adverting briefly to the changes that had occurred during the past year in the Medical School, including the opening of the new physiological laboratories, the lecturer proceeded to his main subject—The Nature and Significance of Pain. Such a topic, he remarked, needs no excuse to a medical audience, for day by day a physiology of the mind assumes more a practical shape. Between physiology and psychology there is still a great gulf; but as the former science progresses the space becomes narrowed, and the time must arrive when the two sciences will begin to merge one into the other. Whence comes the universal liability to pain in mankind? The apparatus required for a sentient being consists of a nerve beginning to receive the impression from without, a nerve to conduct it, and, most essential, a brain to realise it. Possibly in an animal as low down in the scale as the sea anemone the first indication of a nerve is found, for we consider that to be a nerve which discharges the functions of such. In its primitive form it is but a process of homogeneous matter jutting out from a cell placed beneath the integument. A stimulus applied to the extremity of the process produces some change in the central cell, but there is no brain, and therefore no sensation. As we ascend the animal scale the nerves are found to be more distinct and the nerve cells become massed together to form a brain. At some point or another the brain first acquires the dawning power of appreciating impressions, and at some higher point the property first creeps in of realising them; what was below this merely a sensation, above it becomes the idea of a sensation. Pain is only an intense or disorderly sensation, or one that interferes with health or comfort. It follows that of a great number of impressions we cannot say positively whether they are painful or not. In medicine and surgery we have little to do with these "borderland" pains. The impressions are commonly unmistakable. The mind is unable to realise pain as such, and only, as it were, to become aware that it is disturbed by a series of impressions too disorderly or intense for the comprehension. Here, possibly, we may catch a glimpse of the nature of pain, as being the unavailing effort of the consciousness to realise its own disturbance. The phenomena of living muscle instance well the graduation of impressions leading up to pain. Of the muscular movements of respiration we are all but unaware; more powerful contractions, as in athletic pursuits, give pleasure, while intensely powerful contractions independent of the will or control, such as occur in lockjaw, cause agony. Through the senses of sight and hearing the bulk of our education is conveyed to the mind. It follows that intellectual development renders us susceptible to new pains. Highly sensitive people are in fault usually, not in the nerve paths, but in the brain. As we can educate ordinary touch, so we can educate the sense of pain, as may be seen in the case of the so-called hysterical. Pain will be as real in such as in others, for subjective may be at least as vivid as objective sensations. A brain may be functionally as unduly tender as any given part of the body. The world is sorry for the person whose brain is disturbed by the impressions coming from a disorganised joint, and too often only laughs at the patient who has the same disorder brought about by a different condition, yet both are diseased, and indifference or mockery may be to the tender brain as a blow or a jar to the tender joint. The lecturer strongly advocated the study of the mental aspect of disease, especially in asylums for the insane, remarking that such institutions were really special hospitals possessing the unique merit that nothing could be said against them. In commenting upon another aspect of the subject—namely, the conditions which diminish suffering,—the lecturer remarked that pain was necessarily confined to the animal world, the liability being proportionate to the physiological development. As, therefore, this liability increases, so does the capacity of the intelligence, to minimise pain augment. Pain bears no fixed relation to the severity or importance of disease: some almost trifling diseases are attended by a vast amount, other grave disorders with a minimum, of suffering; a toothache may be agonising; and yet a person might have a large aneurysm, or his liver might be saturated with cancer, without his being aware of the condition; so here, if nature exacts, she also grants. It is noteworthy that the value and defensive use of pain is of importance principally at the moment, for there is no real power of recollecting pain. Much is said nowadays on the subject of "preventable diseases"; assuming for the moment that disease and pain are convertible terms, we should regret no less in the clinical work of a large hospital, the waste of energy, the squandering of the utility of existence, the failure to profit by the opportunity of life due to preventable pain. In the wards and out-patient rooms it meets our eyes everywhere; poverty, ignorance, and vice are the great factors. The fallacy is often urged that health cannot be bought; in truth it is a most marketable article. Much immunity from pain or disease might be purchased, for rest is the natural antidote to pain. Where would be the joint and spinal diseases, the incipient phthisis, and the like, if rest could be provided, not merely prescribed? Such patients could be taken in and put on the road to recovery, or at the outset cured, at a shilling a day, if there were adequate hospital accommodation and means to buy health for the poor.

KING'S COLLEGE.

LORD SELBORNE, after expressing the pleasure it gave him to be present on occasions of this sort, said that with regard to what had been said about the establishment of a teaching university for London and the granting of higher academical rank and power to those kindred institutions, he dared say it was a subject attended with difficulties—indeed he knew that it was so from his own experience, for in his own profession he was extremely desirous to see the Inns of Court organised on a footing more worthy of the resources of their historical and privileged position, and, moreover, one likely to be productive of a more scientific

Digitized by Google

and systematic study of law in all its branches. He could not help thinking that in London they had lost by the dislocation of the elements of education, which perhaps by better organisation might be more useful than they were. The University of London as it now existed stood very high indeed, and justly so, among the scientific educational bodies of the world, although it was not a strictly educational body, but a body which tested the results obtained elsewhere and rewarded them with very valuable degrees. Whatever happened, he trusted nothing would ever arise to diminish the value of the degrees of the University of London; but it was quite possible that an immense gain might be experienced for the better organisation of the teaching bodies in London, not only in medicine, but in law and the arts generally, which might either be united or not with the present examining University of London. All being really engaged in the same work, and most successfully engaged in it, he could not but believe that greater things were in the future before them than ever had been yet attained; and if this present movement should have that effect, he thought all good citizens, as well as all well-wishers of university education, might congratulate themselves upon it. In the course of some further remarks upon the comparative position of the professions, his lordship said that the profession of medicine hardly stood much below that of religion, for as a clergyman was always alleviating or applying remedies to the moral sufferings of mankind, so the work of the surgeon or physician was always to do good, and to alleviate those physical misfortunes which accidents or sickness brought to their fellowmen, and he thought they were certainly entitled to one of the most prominent positions among those who did good to mankind.

MIDDLESEX HOSPITAL.

AT Middlesex Hospital the usual custom of having an introductory lecture was departed from, and the session was opened by a distribution of prizes and a reception in the new buildings. The lecture theatre was densely packed with students and their friends, and numbers failed to gain admission. The Dean, Mr. Pearce Gould, read the annual report, which largely consisted of a sketch of the history of the school. From the foundation of the hospital in 1745, pupils were to be found in its wards, and some years later regular clinical lectures were given. In 1819 a room was set apart as a lecture theatre. Long before this, however—in 1773—the students had formed a medical society, which has continued to this day, and is now more flourishing than ever. This society is at once the oldest organisation connected with the school, and the oldest of students' medical societies in the kingdom. The first important connexion of the hospital with a medical school was on the establishment of the famous Windmill-street school, for the pupils of that school obtained their hospital practice at Middlesex Hospital; and when the majority of the lecturers and students migrated to St. George's Hospital, the hospital wards were opened to the pupils of the newly-founded University of London. On the building of University College Hospital in 1835, Sir Charles Bell, Sir (then Dr.) Thomas Watson, Mr. J. M. Arnott, Mr. Mayo, and the other members of the staff, founded "a complete school of medicine in avowed connexion with the Middlesex Hospital, and under the sanction of its patrons." After tracing the gradual growth of the school, the report went on to refer to the new buildings which were opened that day, and which made their accommodation complete. Former alterations and additions had satisfied special wants most pressing at the time, but now they could look round upon their school without the thought that something more would soon have to be supplied. There were theatres, class rooms, laboratories, museums, and library for teaching purposes; and in addition to providing accommodation for the comfort of all their students, they were able to offer to those who desired it the advantages of collegiate life. In reference to the schemes for establishing some source whence students at metropolitan schools could obtain a medical degree, the report stated that the school authorities had expressed their approval of both the plans suggested, as it was thought that either would secure the end in view, "it being always understood that the degree would only be granted after some further examination test than that now necessary for the usual 'Double Qualification,' while less severe and exacting than those conducted in Burlington House." After alluding to the changes in the teaching staff during the year, the success of the students at various medical examinations, the appointment of Dr. Finlay as inspector of examinations in medicine, the success of the school on the river and in the football field, the results of the various class examinations during the past year were read out, and the prizes were presented by the Lord Mayor of London, who afterwards gave a short address to the students. After congratulating the successful men, and encouraging all, he expressed his high sense of the value of the medical profession, and humorously referred to the universality of such a feeling when sickness or accident occurred. From his experience at Cambridge he felt confident that the new Residential College would greatly promote the welfare of the students. His lordship, after the usual vote of thanks, moved by Mr. Hulke and supported by Major Ross, M.P., then inspected the new buildings and the hospital.

ST. THOMAS'S HOSPITAL.

INTRODUCTORY ADDRESS BY MR. R. W. REID, F.R.C.S., LECTURER ON ANATOMY.

MR. REID, after welcoming the new students, said that the life of a medical student may be looked at in two aspects; firstly, in its professional; and, secondly, in its social. To the former of these two he should desire to direct attention. In its professional aspect there are two distinct periods of a student's life—viz., the *first two years* of his course, wherein he studies the structure and functions of man in his healthy state, with the addition of the sciences of botany, comparative anatomy, chemistry, and materia medica, in order to prepare him for the *second period* of his existence, wherein he investigates the human body in its diseased or injured condition, and the proper application of suitable means and remedies to relieve, if possible, this diseased or injured state. He should like particularly to draw a distinct line of demarcation between these two periods of a student's life, and no student ought to attempt to approach the latter without having first mastered the former; or, to put the matter plainly, no student ought to have anything whatever to do with the clinical treatment of disease before he has passed his examinations in the preparatory subjects of chemistry, anatomy, physiology, and materia medica. Anatomy, in its generic sense, is the science which determines the structure of organised bodies, whether dead or living. It resolves itself into vegetable anatomy or botany, treating of the structure of plants; and animal anatomy or zootomy, searching out the structure of animals. The latter divides itself, firstly, into a comparison of the structure of different animals with one another, constituting what is called comparative anatomy; and, secondly, into the investigation of any individual animal, constituting what is known as special anatomy. The anatomy of our calendar means the special anatomy of man as distinguished from that of the lower animals, and in the study of his structure in all its details students are called upon to begin their professional life. It goes without saying that we must understand the structure, appearance, and relations of the constituent parts of a machine before we can understand its working as a whole, or be able to put it to rights if it goes wrong. Similarly, it is evident that we must know the detailed structure of the human body before we can understand the function of its several parts, or attempt to repair it should any of those parts get out of order. As one would expect, therefore, anatomy is the oldest of all the medical sciences. The precise time of its origin is very uncertain. The Egyptian embalmers must have had some knowledge of the human body acquired in the process of the preservation of the dead, but as they were of the lowest order, and, abhorred by reason of their occupation, what knowledge they possessed they kept to themselves, and left no record of it behind them. We may divide the early rise and progress of the science from the fabulous ages to Hippocrates, from him to Galen, then to Vesalius, and then to Harvey, who died in the year 1657. After Harvey's day the School of St. Thomas's Hospital played an important part. Mr. Reid believed that this is the oldest regular anatomical school in England, and, if he said in Great Britain, he believed he was not wrong. Previous to its formation lectures upon anatomy were given at the College of Barber-

Digitized by Google

Surgeons of London (afterwards the Royal College of Surgeons of England) and at the Royal College of Physicians, by members or fellows of either college under the various titles of Reader, Master, or Professor of Anatomy. It is interesting to notice that these posts were, with a few exceptions, held by physicians and not by surgeons, and that Mead, a physician of this hospital, held the office of reader in the year 1711, when he delivered a series of lectures upon the muscles, and thus was one of the first to hold the still existing post of Arris and Gale Lecturer at the College of Surgeons. The practice of the dissection of the human body was introduced into this country by Caius (a name familiar to all Cambridge men), shortly after his return from Padua about the year 1546 or 1547. He first taught practical anatomy in the Barber-Surgeons' Hall of London. To William Cheselden is due the first formation of this anatomical school. After Cheselden, we find, as lecturers upon anatomy, the names of Else, also professor of anatomy at the College of Surgeons; Cline, whom Sir Astley Cooper speaks of "as a moderate anatomist, but sufficiently informed for teaching and practice, a man of excellent judgment, but one whom politics and agriculture have drawn from the contemplation of his profession." We then come to Sir Astley Cooper himself. Cooper taught anatomy and surgery for a period of thirty-five years, in conjunction first with Mr. Cline, then with Mr. Henry Cline, and lastly with Mr. Green. He was appointed Demonstrator of Anatomy in 1789, and resigned the surgery lectureship in 1824. Cooper's name, as far as anatomy is concerned, is chiefly associated with his discoveries in connexion with the lymphatic system, descriptions of the parts concerned in different forms of hernia, and the structure of the breast, thymus gland, and testicle. A number of his preparations showing these different points are still preserved in the museum of St. Thomas's Hospital. He did not confine his attention solely to anatomy in its human aspect, for he was appointed Professor of Comparative Anatomy at the College of Surgeons in 1813. The lectures which he then delivered were the first set of lectures on that subject publicly delivered in London. They related to the classification of animals, and to certain anthropological subjects.

The study of human anatomy may be looked at in two ways:—Firstly, as the means of acquiring a knowledge of the structure of the body, whereby the student is placed upon a platform from which to view the functions of the body in health, and thereby to properly appreciate the effect produced upon the body should those functions become deranged; and, secondly, as a mental training. Mr. Reid claimed for human anatomy not only the study of the parts of the body which we can see by the naked eye, but also the study of minute details, too small to be seen in the ordinary way, but which, when treated with chemical reagents and otherwise specially prepared, become visible by the aid of the microscope. In the latter study, termed General Anatomy or Histology, he warned students not to come to too rapid a conclusion as to what they see when they view a part of the body through a microscope, as frequently the mode of the preparation of the specimen is apt to alter the minute appearances of the parts.

We may study the human body at different periods of its life, from the earliest appearance of the embryo to its fully formed state, and see the successions of forms which it presents at the different periods, constituting what is called Embryology or Developmental Anatomy. This study is extremely important, as by an understanding of it we can explain a large number of the irregularities and malformations to which the human body is liable. Again, we may study human anatomy with reference to the laws which have determined the structure of the body, constituting Morphological Anatomy; and lastly we may study man, or rather the human race, considered as a whole in its separate individuality, and in its relations with the rest of nature. This last branch of anatomical investigation is termed Anthropology. Now, as it is impossible in the matter of time for an ordinary course of lectures upon human anatomy to embrace all these several branches, the student will find that certain of them are relegated to lecturers upon other subjects. Hence he will find that histology and embryology are taught by the physiologists, and that what is left to the human anatomists is an investigation of the structure of the body in its macroscopic as distinguished from its microscopic sense.

As a mental training for the student beginning the study of medicine, Mr. Reid knew of none better than that of anatomy. In the first winter of his course he is called upon to master the subject of osteology. At first, one is apt to be somewhat discouraged by the apparently infinite number of facts, details, and unfamiliar names to be remembered in this branch. He could assure students of the first year, however, that by thoroughly applying themselves to the acquisition of these details their time is not lost; that by so doing they train their aptitude for observation and cultivate their memory. Mr. Reid remarked that of late it has been the practice of some to disparage the subject of human anatomy, for they say it is a worked-out subject, and simply consists in the recollection of a number of details which, almost as soon as they have been acquired by the memory, so soon they leave it. To such persons he should say that human anatomy is *not* a worked-out science, as the recent advances in the knowledge of the structure of the brain and spinal cord, and the exact position of some of the abdominal viscera, testify—advances which have formed the foundations for some of the recent rapid strides in the arts of medicine and surgery; and that the mastering of the so-called number of facts is the most healthy mental exercise the beginner can be put to; for, after all, the arts of medicine and surgery rest upon a basis of accumulated details arranged in their proper order. The sooner, therefore, the student gets into the habit of observing minutiæ, classifying them, and arranging them in such a way that he can thereby be able to draw deductions from them, so much it will be the better for him. He thought that the fault of there being a lack of interest taken in human anatomy does not rest entirely with students themselves, but that both teachers and examiners are greatly to blame. Under the present system teachers (and teachers are obliged to be guided by examiners, whatever may be said to the contrary) are apt to handle the subject as if it were one entirely set apart by itself and having no connexion with any other. They seem to strive to crowd into a short winter's course as many isolated facts as they possibly can, without having due regard to the object in view in the study of these facts. He was sure that if the huge amount of material to be gone over in the short space of two winters were sifted out more into what was important and what was less so, and that if all matter not having some reference to the future work of the student were eliminated from the study and examination of the ordinary "pass man," the labours of the first two years of a student's life might be greatly lessened. As far as the Fellowship and University honours men are concerned, the longer period of three years being allowed for their study, the subject might be treated in a somewhat more purely scientific way, looking at it more from the comparative, morphological, and mechanical adaptation sides—always, of course, presupposing an intimate knowledge of the simpler facts which have peculiar relation to the arts of medicine and surgery.

With regard to the younger and fascinating subject of physiology, Mr. Reid felt somewhat diffident in speaking. Within the last few years it has made such rapid strides, that unless one is in the position of what is called a "pure physiologist," one is hardly competent to say much about it. Physiology is a science which first of all supposes a knowledge of the anatomical structure of the body, and then applies chemistry and physics to investigate the laws of life. Unfortunately, according to the present curriculum, it is found that in the first year of their course students are required to study physiology at the same time that they study anatomy, chemistry, and physics. Happily, however, the authorities require a very elementary knowledge of physiology at the end of the first winter session, so that the student can devote the greater part of his first winter to chemistry, physics, and elementary anatomy. He strongly urged beginners to devote, in their first year, the larger part of their energies to the mastery of the preliminary scientific subjects of chemistry and physics. If they did this, and got rid of them by examination at the appointed time, they would find that they could throw themselves heart and soul, in their second year, to the more immediately medical subjects of advanced anatomy and higher physiology. As far as materia medica is concerned, Mr. Reid confessed that he was obliged to say that *per se* it is a somewhat dry and to the first year's student uninteresting subject. Its place, in the first summer, seemed to him an early one; still it naturally follows a course of chemistry. In its therapeutic sense it is anything but uninteresting, but considered in that sense, its place as one of the subjects of the first summer seemed to him nothing short of absurd, seeing that it implies, or ought to

Digitized by Google

imply, a certain amount of knowledge of physiology and of the different forms of disease, which knowledge the student does not acquire till the second year in the first case, and the third and fourth in the last. However, as his hearers were obliged to devote themselves to the different subjects in the order they were prescribed, all he could say was: Attend diligently to the lectures delivered upon that subject, and take advantage of the thorough and practical teaching in the dispensary of the hospital.

Mr. Reid concluded by recapitulating the facilities which St. Thomas's Hospital affords for students to acquire a knowledge of the subjects he had mentioned, and pointing out the importance of attendance at lectures and class examinations.

UNIVERSITY COLLEGE HOSPITAL.

INTRODUCTORY ADDRESS BY DR RADLIFFE CROCKER.

DR. RADCLIFFE CROCKER commenced by giving a cordial welcome to the new students, and gave them some advice upon the way in which they should spend their time away from the College and in the selection of their companions. In advising them about their work, he began by showing them how not to do it, by describing certain types of students, whose methods did not lead to success, the types selected being the "Casual student," the "Dilettante student," and the "Over-diligent student." He then proceeded to show how the student should do it, and impressed upon them the necessity of being as practical and objective in their work as possible, pointing out that if they neglected their opportunities of learning the use of instruments of diagnosis while students, they could never learn it afterwards, however much they might try, and that thus their stethoscope would become a mere symbol of their profession, like "a portable barber's pole"; while, after all, the best equipped student, when he left the hospital, was not a medical man of experience, but a medical man capable of profiting by his experience. He also urged upon them the necessity of thoroughness and accuracy in the examination of their cases, as it was not so much how many cases they saw, as how they saw them, pointing out that thus a large hospital might become a disadvantage to a student, unless he was careful not to hurry over his cases. He showed how University College Hospital, for example, which was a hospital of moderate size, had, from making the best use of their materials and thoroughly training the student, turned out men equal to any in the profession, and instanced, among those of the present day, Erichsen, Thompson, and Marshall among the surgeons, and Walshe, Jenner, Russell Reynolds, and the late Wilson Fox among physicians, as a proof that it was quality, not quantity, that was essential.

The lecturer then briefly alluded to the necessity of an M.D. degree being accessible to the good average London student, from which he was at present deterred by the high standard and stringent regulations of the London University, and said that the teachers of London were determined that such a degree should be ere long within the student's reach. Passing on to the time when the student had got through all his examinations, and taking up the case of those who sought to go into consulting practice, he showed them what a long and trying time must elapse before practice came, and urged them not to be led into the error of the day of advertising themselves directly or indirectly in order to obtain practice by a direct appeal to the public sooner than they would by addressing themselves to the profession at large, and to look rather to the general practitioner to send them patients; he showed how the advertisers were the least trustworthy men in the profession, and that they for the most part belonged to two classes, ignorant or comparatively ignorant men, who yet made great pretence of knowledge, and whom he denounced as quacks, although they were in the profession, while in the other class were men of ability who were in such haste to be rich that they could not wait until practice came through legitimate channels, and though they doubtless cured their patients eventually, they secured as much money out of them as possible. Further elaborating the subject, he classified the advertising part of the profession on the principle Touchstone used in the gradations of quarrelling, and described humorously the "Advertiser Churlish" as the man who wrote works in which he made out everyone to be wrong but himself, professing to have made discoveries which the blindness and narrow conservatism of the profession prevented it seeing and adopting, and when patients had been previously treated, depreciated directly or indirectly their former adviser in order to exalt themselves. The "Advertiser Valiant" was a man who paraded his ability to cure obstinate or incurable diseases, such as consumption, cancer, &c., and ascribed his success partly to being always ready to make the more serious diagnosis even in comparatively mild forms of diseases, and thus he was credited with curing phthisis, or whatever the disease might be, without really deserving it; further, even if he failed, he was always having a succession of new patients through his advertisements. The "Advertiser Quarrelsome" took the form of writing pamphlets against the abuse of various drugs in the treatment of disease or against operations in various surgical affections, and claimed to show how he avoided all such dangerous methods, and yet cured his patients more quickly and safely. The last two were, the "Advertiser Direct" and the "Advertiser Circumstantial." Pointing out that very few went so far as to advertise themselves directly, as they ran too much risk of being expelled from the profession, he described the "Advertiser Circumstantial," who, while appearing to praise something else, was really putting himself forward. As the most flagrant instances, he mentioned men who lent their aid in puffing sundry trade articles, either directly, by writing testimonials to the vendors, or indirectly, by allowing extracts from their works to be reprinted by the vendors of drugs, foods, or hygienic articles, and sent round as circulars, or left in public places. Another plan was to write works known as "bread-and-butter books," of more or less pretension, on common diseases, such as "gout," or some fashionable new treatment, such as "massage," to give the impression that they are authorities on the subject; and he urged the public to be more ready to listen to the advice of their family practitioner as to whom they should consult, rather than be led by these plausible writings, of whose merits they were not competent judges to choose for themselves. He felt, however, that in the face of the support that the public gave to quack nostrums, systems, and unqualified pretenders outside the profession, they did not seem likely of themselves to discriminate as to who were or were not the quacks within it. At the same time, he feared that the profession were not as active as they might be in labelling these men as they deserved. He urged that they should refuse to meet them in consultation more than they did, and that they should shun their acquaintance; that men of repute should be more careful how they allowed their names to be on the consulting staff of special hospitals, often started by inferior men to serve their own ends; that medical societies should not only exercise care in admitting their members, which he acknowledged they did, but that when men advertised, and in other ways showed themselves unworthy, the offending member should be summoned before the Council, and, if necessary, expelled, and gave an instance in which this had not been done in a flagrant offender. Similarly, that licensing bodies should always exercise to the full all the powers they possess to stop those who offended, even when the advertisements were not absolutely direct.

The lecturer concluded by warning those who sought to do consulting practice that they must be content to wait some time before they could make a reputation amongst their medical brethren, who could judge of the merits of their work in societies and other scientific meetings, from communications to medical journals and *bonâ-fide* works, which would lay a surer foundation for their reputation than that which they might get from ephemeral popularity. He exhorted them, one and all, not to let money-making be their sole aim, nor to allow, as a French writer put it, "their conscience to be a watch regulated by the clock of the parish," but, in the words of Polonius to Laertes,—

> "This above all—to thine own self be true:
> And it must follow, as the night the day,
> Thou canst not then be false to any man."

ARMY MEDICAL SCHOOL.

THE winter session of the Army Medical School was opened at Netley on Monday, the 3rd inst. The introductory lecture was delivered by Professor David Boyes Smith, M.D., F.R.C.P., who in his discourse gave a review of the valuable work done in various departments of science by

Digitized by Google

medical officers in India. During the present term there are no candidates for commissions in Her Majesty's British Medical Service, but, in their stead, twenty-three commissioned medical officers have joined to attend the courses of instruction. The same number of candidates for commissions in Her Majesty's Indian Medical Service also joined the School on the 1st inst.

ROYAL VETERINARY COLLEGE.

PROFESSOR THOMPSON LOWNE, F.R.C.S., in delivering the introductory lecture, said that the use and progress of scientific veterinary practice in this country had been exceedingly rapid. He remarked upon the petty jealousies that had arisen between two sister professions so knit together in a common cause, so unlikely to clash in interests, as the medical and veterinary, and said that in Germany the two professions were far more intimate than in this country, but he believed that the time was at hand when they would follow more closely the good example of their continental neighbours. Their knowledge of the causation of contagious epizootics had recently made vast strides. The discovery of the existence of all-pervading organisms, better known, perhaps, as disease germs by the laity, and the potency of these for harm both to man and animals, had thrown a new light upon contagious epidemics and epizootics, but there was still much to be learned in this direction. It was obvious that such matters could only be set at rest by prolonged and careful experiments extending over long periods of time. He was aware that such experiments had been recently carried out by the principal and his staff, and that a distinguished German, Professor Schutz, had been working in their laboratory. But there was less activity in forwarding knowledge of such methods in this country than could be desired. Lack of money set aside for such purposes was one of the causes of this. Our own apathy and carelessness were not worthy of the richest country in the world. There was another check upon original research in this country. The so-called Vivisection Act was in his opinion much to be deplored, as great difficulties were thrown in the way of all experimenters, which could only be overcome partially by a few men of known scientific reputation, so that original research into the causes of disease was seriously crippled in this country. Thousands of animals perished from such diseases as anthrax, rabies, diphtheria, consumption, and similar epizootics; man himself fell a victim to many epidemics; and yet such a mistaken policy threw every obstacle in the way of those who would fight the good fight against disease and death, even at times at the imminent risk of their own lives.

SHEFFIELD SCHOOL OF MEDICINE.

INTRODUCTORY LECTURE BY DR. SINCLAIR WHITE.

THE introductory address was delivered at the Firth College on Oct. 3rd.

Dr. White began his lecture by welcoming the new students who were about to enter the Sheffield School of Medicine. They were entering on a career second to none in point of interest, and equalled by few in point of usefulness. Although some other callings offered more tempting prizes, from a pecuniary point of view there were not many in which the risk of failure was less, provided the student possessed a fair amount of industry and health. He pointed out that medical science is a hard taskmaster and has no place for idlers, and that all who wish to attain eminence therein must toil on from point to point, until they have scaled the steep acclivities which lead to wisdom. In such a journey the quality that tells most is that of perseverance. A quick intellect and a retentive memory are valuable endowments; but the race is a long one, and the plodding man succeeds best in the end. Exactitude and thoroughness should be aimed at in all things, because, if a thing be worth doing, it is worth doing well; and the habits formed during student days form the groundwork of the character in after-life. Before another year had arrived a new medical school would be ready for use. This munificent gift they owed to the generosity of his senior colleagues and a liberal public. With the new students, and those who were to follow them, rested the opportunity of making it worthy of the efforts of its founders, and an institution of which their fellow-townsmen would be justly proud.

Dr. White devoted the greater part of his address to the subject of sanitation. As medical officer of health his position entitled him to speak with some degree of authority on the subject, and the occasion seemed a suitable one for urging the claims of sanitary science. After relating briefly the history of sanitation and dwelling on the achievements which hygienic reforms had brought about, he warned his hearers that the struggle against disease was a never-ending one. Lurking in our midst, in spite of all our boasting, there is much preventable disease, while the rapid growth of towns accentuates all the evils incidental to the aggregation of large communities. Hitherto the votaries of sanitary science have been drawn mainly from the medical profession, but the aims of the subject are far too great and good to remain a monopoly of any particular section of the community. Every true-hearted man must feel that to improve the physical, the social, and, indirectly, the moral condition of his fellow-men, to prolong life, and to curtail sickness, with its attendant poverty and misery, are objects worthy of his best efforts; indeed, looked at in this light, the aims of sanitary science are not very different from practical Christianity. Let those who come much in contact with the worst stratum of society reflect whether it is not a useless task to try to improve the social and moral character of these people, unless at the same time something be done to lift them out of the squalor in which they literally grovel. Let us go into their midst, taking heed where we walk, and, after having noted well their homes and surroundings, ask ourselves if it is possible to bring up children with pure minds and healthy morals in such places, where common decency itself is outraged. Without pausing to discuss whether the moral and social degeneracy of these people is the cause or effect of their squalid homes, it is sufficient to note that wherever filthy dwellings, foul air, and insanitary surroundings abound, there we are sure to find social and moral degradation of the people. It is unreasonable to expect pure water from a filthy spring; and sanitation must precede every other gospel if we would rescue these people from the depth of ignorance and depravity into which they have fallen. Give them more light and air in their homes, remove at once from their midst all forms of filth, provide for them paved and clean yards, and teach them that cleanliness is essential to self-respect. Then, but not until then, we may look with some degree of hope for the social and moral improvement in these people. There are a number of subjects connected with public health which still require parliamentary interference, but he who thinks that the mere enactment of sanitary laws will make the people more healthy is doomed to disappointment. The real remedy is to shed more light on God's laws. Men and women must be taught that it lies in their power to live longer, healthier, and happier by observing these laws; that cleanliness is essential to goodness, and even to godliness; that they have a mine of health in fresh air, soap and water; that the best heritage they can bestow on their children is a robust constitution; that intemperance, whether in eating, drinking, or in any other respect, is unmanly, degenerating, and suicidal; that infectious disease can be avoided, and that it is incumbent on them to avoid it by every known means; that as the fountain must be clean before pure water can flow, so the homes and surroundings of the poor must be cleansed before we can expect social purity. The task is an arduous one, but the objects to be attained are worthy of the struggle. The lecturer then alluded to the national and economic value of sanitation, pointing out that every healthy life was of a certain value to the State, and that preventable disease and death were enormous drains on our national wealth. The ever-increasing preponderance of town populations over that of rural districts had a tendency to reduce the physical vigour of the nation, and it was more than ever necessary that the conditions inimical to health and vigour in our large towns should be reduced to a minimum. Reference was made to the great amount of ignorance, even among the educated public, on hygienic matters, and the failure of the Educational Department to teach hygiene in elementary schools. The lecturer concluded by urging on his fellow-townsmen the desirability of forming a sanitary association in the town.

NEWCASTLE COLLEGE OF MEDICINE.

THE winter session of University of Durham College of Medicine was inaugurated on the 4th inst. in the Wood Memorial Hall. Dr. Heath presided, and the prizes were distributed to successful students by Sir Lowthian Bell, F.R.S. The civic authorities were represented by the Sheriff of Newcastle. The Wood Memorial Hall, it should be explained, does not belong to the Medical College but to the adjacent building of the Mining Engineers. This will make Dr. Heath's opening remarks more intelligible to outsiders. He said "it was probably the last meeting of that description that would take place in that fine hall. That was not because their friends—the mining engineers—were less likely to be generous and liberal to them in the future; but because he hoped before next October to be in a hall of their own, as handsome as that and larger, and, he trusted, more convenient for their purpose. They were, in fact, about to leave their own home and to enter new premises, where they hoped to be as fortunate and successful as they had been in those they had hitherto occupied. They were absolutely engaged in the erection of a new college, which they trusted would be an edifice not unworthy of the city of Newcastle. They proposed to establish in it a new department, which they hoped would be of great public utility, and that was the department of comparative pathology, which was a branch of a much wider subject which had been discussed for the last thirty or forty years, and which had greatly occupied the attention of the medical profession, aiming as it did at searching out the origin of disease and its cause, and destroying it at its root."

THE PROFESSION OF MEDICINE IN JAMAICA.

SOME three years ago the people of Jamaica imported into their island the machinery of popular government, and acquired under the electoral law which was then passed by the local Legislature a very broad scheme of representation. Among other results of the important change thus effected in the constitution of the governing body have been some which seriously affect the standing and prospects of medical practitioners in the colony, and are of special interest to Englishmen who may contemplate making the island the sphere of their work. In order, however, to explain the present position of the medical profession in that part, it is necessary to give a short history of the relation of the State to the art of medicine for some few years past.

Ten years ago the Government awoke to the fact that the sparse and scattered population over which they ruled was very ill-provided with medical attendance. The state of things which then existed there is difficult of realisation by English readers. The case of an English rural district presents no parallel. The few medical men who had established themselves in the island were for the most part settled on the coast, and over a large proportion of the country districts it would happen that the nearest doctor would reside twenty or thirty miles away. The natural and obvious consequence was that the health of the community was sadly neglected. Private ignorance, if we may use the term, kept the rural population undefended and an easy prey to all the maladies that, in a tropical country, attend upon insanitary conditions, and official ignorance of the state of the public health in parts remote from the capital paralysed the efforts of the Government to cope with preventable disease. It was natural and wise that in such circumstances the Government should adopt a scheme for promoting the settlement among the rural population of a sufficient number of medical men. The earliest efforts made in this direction need not now detain us. Suffice it to say that they were not conspicuously successful, and in 1871 Deputy-Surgeon-General Mosse, C.B., of the Army Medical Staff, was appointed chief of the local medical department, and entrusted with the work of reorganisation. The scheme adopted by the Government under the advice of this distinguished officer was, broadly, as follows:—

English medical practitioners were invited to settle in the colony on the footing of members of the Colonial Medical Service. Their duties in that capacity would embrace "the medical charge of paupers on the parochial rolls, and of any hospital, almshouse, or prison in their districts"; they would be further required "to attend upon the constabulary; to exercise a general control and superintendence of the Government dispensaries of their districts; to vaccinate; and to advise the Government and parochial authorities on questions affecting the public health." These duties, though multifarious, were not too onerous to permit of simultaneous attention to private practice. Indeed, in the scheme put forward by the Government the private practice figured as the chief field of the medical man's labour and the principal source of his emoluments. The stipends offered by the Government were fixed at amounts varying from £150 to £250 a year; but, at the same time, it was stated that the value of the private practice would vary from £150 to £600, and the exact relation in which the medical man was to stand both to the Government and the population was accurately defined in the following terms:—"The district medical service of Jamaica is, in fact, to be regarded as a system in aid, the object of which is to diffuse medical assistance throughout the several parishes by inducing practitioners to locate themselves in districts which without some contribution from the Government would be altogether destitute of aid and advice, and the pay received by the medical officer from Government may be regarded as a retainer for professional services to be given as a private practitioner within the area in which he resides."

Such in its main outlines was the scheme of 1881. There were details, to which it is not necessary to refer particularly, conceived in the interest of the medical staff, which would of course suggest themselves to the mind of an old army medical administrator like Dr. Mosse. Two of these minor points, however, should be mentioned in passing, as they have a particular bearing on the controversy which has unfortunately arisen. These were the exercise of Government control over the local practitioner exclusively through the superintending medical officer; himself of course a medical practitioner of eminence; and the provision of a small pension upon retirement.

This scheme obtained the professional popularity which it deserved. A sufficient staff of thoroughly capable medical men was secured; the country was portioned out into districts measuring about twelve or fifteen miles across, so that medical aid, if not exactly brought to every door, was at least brought within reach; and, what is only less important, every district was provided with its own officer of health; while the several officers, on their part, were made responsible for districts large enough no doubt to require constant attention, but not too large to permit of their doing justice to them.

There was, however, one weak point in this generally excellent scheme. The duties of the medical officer had been somewhat loosely defined, and there thus arose the risk of these duties growing, little by little, more and more onerous without any corresponding increase in the medical man's emoluments, so as in the end to interfere seriously with the private practice which he had been encouraged to look for—which, indeed, originally afforded the principal reason for locating him in his district. This state of things has actually occurred. In some measure the result has come about spontaneously, as one may say. It is the fate of public officers in all parts of the civilised world to be called upon to furnish the Government with multifarious returns, and it is nowise surprising that there should be a gradual extension of the demand for returns as time wears on. This of itself has attained proportions in Jamaica which have long made the members of the medical profession there feel it to be an irksome and even oppressive task. Yet at its worst this is a comparatively small matter, and it is one which might be expected sooner or later to be satisfactorily arranged. The more serious ground of complaint has arisen upon the recent action of the Legislature in connexion with a reform of the Poor Law.

It is easy to understand that the relief of the poor is a matter of some considerable importance in Jamaica at the present time. The island, like other countries which depend for their prosperity in any considerable degree upon the sugar market, has suffered seriously from the depression of late years. Quite recently, also, there has been a falling off in the demand for labourers for the Panama Canal, and that has closed an important channel for the relief of destitution. Still, Jamaica is not nearly so badly off as some other of the West Indian Colonies. It has the capital advantage of

Digitized by Google

possessing an assortment of staples, and cannot therefore be reduced to extremity by the failure of one. Thus it has happened that growth in the fruit and coffee trades, for example, has done much of late to compensate the community for the shrinkage of the trade in products of the sugar-cane. We in England, however, have good reason to know that compensations of this kind go hand-in-hand with much individual and class suffering. The community, as a whole, is much more versatile than its members, whether taken as individuals or as groups; and thus it happens that the hardship falls upon one part, while the compensation alights on another part, of the body politic. The remedy, so far as legislation can afford a remedy, is found in distributing the burden of poor relief as widely as possible over the community. But this principle the Jamaican Legislature does not seem to have adequately grasped. By a statute recently passed—Law 6 of the year 1886—the Poor Law of the island was remodelled, and a large and very undue proportion of the additional burden was cast without any valuable consideration upon the shoulders of the medical staff. Thus, by Section 29 of this statute, the district medical officer is required—(1) To make a monthly return of the sick poor to the parochial board; (2) to examine in a prescribed manner any person in the receipt of poor relief or any applicant for poor relief whom he is by the inspector of the poor requested to examine; (3) to give to the parochial board and to the inspector, when required, any "reasonable information" respecting paupers under his care; (4) to make such written reports as the central or the parochial board shall require relative to any sickness prevalent among the poor of his district; (5) to attend the parochial board meeting when summoned; and (6) to give written certificates, when required, to the parochial board or inspector of the nature of any pauper's illness.

Some of these duties, such as examining paupers and attending parochial meetings, are very onerous, involving, it may be, considerable travelling, in addition to the expenditure of time and energy upon the work itself. Yet all these are added to the duties heretofore discharged by the medical staff on the strength of the Government "retainer." But the time has assuredly gone by when this term can be applied to the allowance which is no longer even a liberal remuneration for the duties imposed. But while, on the one hand, the Government has derogated thus seriously from its own grant of a retainer, it has, on the other hand, pressed the theory of a retainer to the furthest point—so far, at least, as new members of the service are concerned—by binding them to a prescribed scale of fees. Such interference with individual freedom of contract, if justifiable at all, can be justified only on the ground of a special right to dispose of the services of medical men derived from the Government subsidy, and when that subsidy has been converted by the annexation of onerous conditions into a bare equivalent, the interference is convicted at once of being destitute of even the shadow of a just and sound foundation. Where in matters of so great moment the Government has shown such an absence of faculty to appreciate the equities of the position, it is not surprising to find that they have also withdrawn the advantages, which were granted in connexion with the earlier appointments, of a retiring pension and the mediation of a chief medical officer between the Government departments and the district medical man. These things add considerably to the dissatisfaction of the medical profession in Jamaica, and they make the prospect a very undesirable one for the men now and hereafter joining the staff. Altogether it may be admitted that the Jamaican Legislature displays a certain zeal for economy in the public service, but it is not "according to knowledge," and the result of the very inequitable apportionment of burdens to the medical practitioners in the colony can hardly fail to seriously affect the efficiency of the profession there.

SOCIETY FOR THE STUDY OF INEBRIETY.

A QUARTERLY meeting of the Society for the Study of Inebriety was held in the rooms of the Medical Society of London on Tuesday last, the president, Dr. Norman Kerr, in the chair.

Dr. E. P. Thwing, New York, read a paper on American Life as related to Inebriety, in the course of which he stated that the disease of inebriety, apart from the vice of drunkenness, was more prevalent in America than in England, was more rapidly developed, and attained to a higher degree of intensity. Americans could not stand liquor as Englishmen could, and the same greater susceptibility to the action of other narcotics prevailed. Turks, Hollanders, and Chinese could use tobacco and opium without impairing their eyesight, but Americans suffered in heart and brain, eyes, teeth, muscle, and nerve. This heightened American nervous susceptibility was the result of combined physical, psychic, political, and social conditions. For example, there were on that continent extreme thermal changes, he having known a leap in twenty-four hours from torrid heat to frosty chill. Political campaigns, with their brain pressure, contributed largely to inebriety. Over-pressure in education, the emulous rivalries of business life, speculation, and the national headlong rush through life, all acted powerfully in the production of the enormous development of the disease of inebriety in the United States.

The President narrated several cases observed by him in America twenty years ago, illustrative and confirmatory of Dr. Thwing's propositions.

Mr. Walter Kennaway treated of Asylums for inebriates in New Zealand, pointing out that, when the inebriate's brain was so sodden and saturated with poison that it had lost all sight of moral perspective, there was but one rational mode of cure. There must be deprivation of freedom and removal from present surroundings to rid the system of the poison and allow the will to recover its tone.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASE.

To the Editors of THE LANCET.

SIRS,—The letter in your issue of last week from Dr. McLiesh ought not be allowed to pass without the presentation to your readers of the other side of the question of compulsory notification of disease.

In Reading, a borough until lately with a population of nearly 50,000, and recently enlarged to include 60,000, compulsory notification has been enforced for six years, with, according to my experience, the cheerful acquiescence and hearty co-operation of not only the medical practitioners, but also of the laity within the municipal jurisdiction. Undoubtedly the successful institution of this necessary safeguard, its good reception by practitioners and the public, and its subsequent smooth working have been mainly due to the tact and temper of our lamented colleague and friend, the late Dr. Shea, medical officer of health, who with rare professional qualifications for his official position combined unusual powers of conciliation and persuasion. He, appreciating the difficulties likely to arise from the delicate and confidential relations subsisting between practitioner and patient, wisely imposed a *dual* responsibility, by which, under a penalty of ten pounds, notification of infectious disease has to be made both by the medical attendant *and householder*, the former receiving a fee from the sanitary authority for his certificate. I apprehend from Dr. McLiesh's letter that the conditions at Bolton are different, in that, instead of the responsibility of notification being mutually shared, the householder is entirely relieved, and the whole onus thrown on the medical attendant. Herein lies the obstacle to the smooth and effectual working of the system at Bolton. Nor would the difficulty be obviated by throwing the reponsibility on the householder alone. In the former case the doctor is placed in the invidious position of an informer, while in the latter the temptation is presented, through prejudice, to dispense with medical supervision, and conceal the existence of infectious disease. The success of compulsory notification of infectious disease in Reading, is, I believe, chiefly due to this plan of imposing a double obligation respecting it, and, wherever the system may be adopted, I would urge that this condition is essential to its favourable reception and the avoidance of friction. Something, of course, depends on the relations existing between the practitioners of the district and the medical officer of health, and these will be pleasanter if he devote his whole time to his duties and do not compete with them in private practice. In conclusion, I believe I am warranted in asserting that, subject to the condition of double obligation, the medical profession in Reading emphatically approve of compulsory notification as being greatly to the public advantage. I am, Sirs, yours faithfully,

Reading, Oct. 3rd, 1887. J. HOPKINS WALTERS.

THE LANCET.

LONDON. SATURDAY, OCTOBER 8, 1887.

WE are quite disposed to agree with a remark of Dr. HANDFIELD JONES at the opening of St. Mary's School on Monday, that the Introductory Lecture is a thing to be maintained and approved. He was speaking with special reference to Mr. CRITCHETT'S address. But, without any special reference, it seems fit that young men entering the great Temple of Medicine, and preparing to devote their life in its service, should be reminded of their high calling and of all that is needed to constitute medical character and to enable them efficiently to do medical work. Life is prosaic enough, and medical education in its details is apt to be somewhat dry; so that it is a kindly thing in one who has the power or the right to utter words of encouragement and inspiration, and to point out how the most prosaic of duties may be made interesting, and the driest of studies a means of enjoyment. There are students in whom the sense of duty or the love of work is strong enough to make them independent of such encouragement, and there may be others on whom all such influences are thrown away. Neither of these classes can be injured by an Introductory Lecture; and certainly neither of them constitutes the bulk of medical students, with whom a word fitly spoken on an eventful day in their history is likely to have very lasting consequences. No doubt the behaviour of some audiences at the Introductory is irreverent and disrespectful. So is the behaviour of the classes of many teachers; but this is often the fault of the speaker, and depends on the absence of that subtle quality of authority which is itself a gift, and which makes the class rooms of some men as decorous as a church. The individual addresses of this year embraced as usual a great variety of subjects. They should all be read by those who would learn the great fact that medicine is a large, many-sided subject, linking together individualism and society, body and mind, nature and art, man and the whole inferior creation. It would be invidious to make distinctions when each contained so much. Some of the lecturers were specialists of eminence, but their specialism was not obtruded. One could scarcely have told that Dr. CROCKER was a distinguished dermatologist, so broad was the basis of his eulogy of University College, and of such universal application was his advice to students to trust for reputation and success only to such work as would stand the judgment of men of their own profession and carry their approval, and his definition of quacks and advertisers of all sorts, whether in the profession or outside it. Mr. CRITCHETT, indeed, in his admirable address, did betray his affection both for his specialty and for one who was one of its greatest ornaments; but he did so in terms of perfect taste and much interest, and, taken as a whole, his account of the medical art and the means by which it is to be learnt and practised, was wonderfully proportioned and complete. Nor should we omit one word of remark on the silence and attention with which it was listened to. Dr. STURGES, in common with several other lecturers, discussed the burning question of a degree for London students, giving it the larger form of a true Teaching University for London. As might have been anticipated, his treatment of the subject was critical and discriminating, and may well be studied by all who are interested in this pressing matter. Equally worthy of attention were his observations on the examining bodies, and their supervision by the Medical Council. We hope he is not too sanguine of the good to be achieved by the Inspectors created by the new Act who have an enormous work to do in a very short time. At St. George's, Mr. DENT discoursed on a well-worn, but mysterious subject, the Nature and Significance of Pain, and he contrived to bring his scientific thoughts on the subject to a most practical conclusion. He made mincemeat of those who sit down in despair, and regard pain as inevitable and incurable. He magnified the discoveries which abolish pain for great surgical purposes. But beyond this he declared that health was "indeed a most marketable commodity," and that a shilling a day would procure for thousands much immunity from pain. Such cases as those of joint and spinal disease, of incipient phthisis, he maintained, might be relieved and saved if the rich and the strong would come to their help, and to the support of those medical charities which contemplate their relief. Mr. REID'S lecture at St. Thomas's was one of the best in its suggestions as to the course of medical education, and in its history of anatomical teaching in particular. Sir ANDREW CLARK presided, in the unavoidable and regretted absence of Mr. JONATHAN HUTCHINSON, at the dinner of the London Hospital School, inaugurating the splendid new buildings, which, as Sir ANDREW said, do so much credit to all concerned — the architect, the medical staff, and the house committee. Sir ANDREW descanted with characteristic eloquence and with justifiable pride on the history and work of the school, and on the proofs on every side of its vigour and capacity to adapt itself to new conditions. In common with Mr. PEARCE GOULD at the Middlesex, he boasted that his hospital was one of the earliest to use hospital cases for purposes of clinical teaching. We may leave two such good-natured combatants to say which was first. Both were doubtless early in the field. We want more information about the methods of medical teaching in London a hundred and fifty years ago. For most men who did not go to the Scotch or the foreign universities it doubtless consisted chiefly of apprenticeship with a barber-surgeon. Very different is the case of the students of to-day in London, who have a field of observation and study unequalled in the empire, and whose teachers vie with each other in demonstrating the last improvements in art and the last discoveries in science. If the students of to-day do not learn their profession, and if they fail to practise it with dignity and efficiency, it will be their own fault.

WHETHER a lunatic be criminal—as is quite possible—or a criminal be lunatic, it is undoubtedly undesirable that the leaven of that terrible compound, criminality and lunacy, should be allowed to permeate the lunatic population which has not already been contaminated by criminality. It is important to distinguish between criminality, or the potentiality of crime, and crime itself. Much nonsense has been, and still is, talked by eminent scientists who do not make

Digitized by Google

this distinction, and consequently fail to discriminate between overt acts of law-breaking and the underlying state of mind which frequently, though by no means always, finds expression in crime. A "nature," or "mental constitution," or "moral character"—call it what you please—may be criminal and never bear fruit in overt acts against the moral or legal code of society. We are speaking of what religionists designate "the depravity of human nature." Of that science can have no knowledge, except as a fault of development. What we mean is a bias towards the gratification of passions and desires on purely selfish impulses, and in defiance of gregarious or social rules and considerations. We say that this bias may exist in a very high degree, and yet be held in abeyance by motives of interest or fear; or perhaps there may be disabilities of a mental sort—for example, lack of will power and purpose or downright stupidity—which prevent this criminality from bearing fruit in crime. What we want to make clear is that this potentially criminal selfishness, which is the germ of crime, is not *morbid*, and has nothing whatever to do with "mental disease" properly so-called; and those who confound the two things do discredit to common sense and detract from the *social* value of medical science by making it unpractical. We deny that it is scientific to class all departures from what is conceived to be the normal type of sane humanity as insane. There are many variations, whether of insufficiency or excess in development, which make men either "brutal" or "angelic" in their natures, that are not in any scientific sense faults or unsound. Monsters, both giants and dwarfs, in "mind" so-called, as well as in body, may exist without disease. The cannibal or earthman is not a lunatic, nor is the highly-developed theosophist or spiritualist necessarily insane. Meanwhile it is possible that the subject of an exceptionally variant nature may be both potentially criminal and insane, and when these two qualities coexist in the same individual, the compound is not simply noxious, but pestilent. It seems to put on specially vicious characteristics, and to originate a poisonous principle by which the weak nature with which it is brought in contact may be contaminated and debased. A little leaven leaveneth the whole lump, and it is inimical to the well-being of society that the criminally insane, or the insanely criminal, should be allowed to go at large, even though they may chance to be what is termed "harmless."

Provision ought unquestionably to be made for the safe custody of criminal lunatics of all classes apart from the non-criminal insane. It is in the last degree impolitic to incur the risk of creating the pestilent compound of potential criminality and mental unsoundness, to which we have just alluded, by discharging prisoners who have either become insane since the commission of the crime for which they were imprisoned, or were of unsound mind previously, into the ordinary asylums of the country. It is no true economy to spare the expense of providing special accommodation for "criminal lunatics," at the contingent cost of that contamination which must ensue when the weakly-minded, and therefore presumably susceptible, asylum population is exposed to the influence of natures which are both criminal and insane. It is to persons of this class that such suggestive remarks are made in the wards of asylums as—"If you were to kill him they couldn't do anything to you, because you are insane," or "The knives are blunted that you may not cut anyone's throat with them." Professor SHEPPARD, of King's College, long ago drew attention to the large proportion of persons in whom there is a minimum of insanity with a maximum of vice or criminality. It is a fact that much mischief is being done by the leaven of criminality in the insane population, and the matter is one to which the attention of our legislators ought to be directed without longer delay.

THE anti-vaccinationists of Leicester are greatly discomfited. The simple facts disclosed by our Commissioner, that vaccination and revaccination are the front line of defence in Leicester, as in every other place, against a disease which apart from vaccination mocks the most perfect sanitation, have acted like a bombshell on those who claim the liberty to have small-pox and to give it to others. Mr. BIGGS especially seems to wince under the publication of facts which so convict him of inaccuracy as a historian when he penned his famous sentence that no fewer than twenty-four importations had been stamped out in Leicester "by *sanitary measures alone*," omitting the information to the public that all officials were revaccinated, and that persons exposed to the patients were at once revaccinated by the Leicester authorities. Other writers of Mr. BIGGS's school make no attempt to invalidate our Commissioner's statement; Mr. BIGGS does. But he leaves the facts essentially where our Commissioner left them. He does not deny that the officials generally are protected by vaccination and revaccination, though he has been told by someone that the matron is an exception. We shall require some explicit particulars of the matron's case before attaching any importance to Mr. BIGGS's alleged exception, which does not invalidate the rule of practice at Leicester. Even Mr. BIGGS does not deny that the matron is vaccinated. She may even have been revaccinated, too. But she is not an unprotected person, like the hapless babies that to the number of 2000 a year are accumulating in Leicester. We have, by the way, before us another proof of the carelessness of Mr. BIGGS's statements. In his letter to the press Mr. BIGGS allowed himself to say, and to glory in the supposed fact, that there were only thirty-nine vaccinations by private practitioners in Leicester in 1886. The argument was that the intelligence of Leicester was losing its faith in vaccination. A return by the clerk to the guardians states explicitly in a note that of the 598 vaccinations in Leicester in 1886, 344 were done by private practitioners. Mr. BIGGS quotes the late medical officer of health as saying that he would undertake to stamp out small-pox without recourse to vaccination. He does not contradict the statement that this gentleman is revaccinated. He even tells us that he is an ardent advocate of vaccination. We leave Mr. BIGGS any consolation he can get out of the facts concerning the late medical officer of health's speculative views—a protected person and an ardent advocate of vaccination. We attach more importance to his example of guarding himself by vaccination and revaccination. Does the present medical officer of health help him? Let the public remember that our Commissioner's statements are

Digitized by Google

based on information received from the medical officers of health, past and present, who know what is done better than does Mr. BIGGS, and that Mr. BIGGS himself does not pretend to adduce any contradiction from them of our main statements. The last report of the medical officer of health, published since our Commissioner's visit, and alluding to the Commissioner's visit, contains no contradiction, but a very practical recognition of his statements, with an actual illustration of the practice of revaccinating exposed persons. Mr. BIGGS says that all our statements and those of our Commissioner are based on the admission of a tramp and the revaccination of two paupers. Our Commissioner never mentioned the two paupers. Our proposition is that exposed persons, including the sanitary, medical, and nursing staff, and friends of the patients, are protected by vaccination and revaccination, and Mr. BIGGS does nothing to invalidate this statement. In another sentence of his letter to *The Times* he seems to attribute to Dr. CORY the belief that the safety of the 140,000 persons in Leicester depends upon the casual and perfunctory vaccination of two paupers. Neither Dr. CORY nor we hold any such opinion. Such safety as they have is due to vaccination primarily, but the population of Leicester are in a state of great danger, to be tested whenever they shall be exposed to the disease—as may happen in any casual train or place, or whenever the cordon of vaccinated persons is withdrawn in Leicester. It is nothing wonderful that when small-pox is kept out of their way people do not take it. Neither let Mr. BIGGS delude himself with the idea that we trust to vaccination alone. The great majority of the present generation are vaccinated. Many of them, as he says, take small-pox, but so mildly that only 9·37 per cent. of such die of the disease, against 45·2 per cent. of the unvaccinated. We trust to revaccination, and ask Mr. BIGGS to explain how it is that in the small-pox hospital at Highgate for the last fifty years the officials of the hospital have, thanks to revaccination, enjoyed absolute immunity, with the one exception of a temporary gardener, who, *refusing to be revaccinated*, took small-pox and died. There is no answer to such facts. Are we to be told of the things which follow vaccination? What about the things that follow small-pox? There is no proportion between the slight risks of vaccination and the certain risks of small-pox, as every intelligent inquirer must admit.

WE publish in another part of this impression an account of some important changes that have recently been made in the conditions under which the profession of medicine is exercised in Jamaica. The matter is one which does not by any means exclusively concern practitioners domiciled in the island. For many years past Jamaica has drawn its medical recruits principally from our schools, and the alterations to which we now draw attention, involving as they do the loss to the profession there of very substantial and very considerable advantages, mean, among other things, the closing of a possible career to many of our more promising young men. This is to be regretted on all hands. It is indeed true that the conditions of practice in the island may be insufficiently attractive now to the class of men who have heretofore looked in that direction, though it will still afford a refuge for those who are less qualified for the fiercer competitions of professional life. The better prizes go to the better men as a rule, and the lesser prizes to those of less desert. So far as it is a mere question of a market for professional services the difference is not great. If the more ambitious do not crowd into it, there is more scope for the less ambitious who do; and seeing that we are bound to have various degrees of attainment among the men who take medical qualifications, it is not altogether displeasing to find that there are consolations for the inferior men as well as rewards for the more brilliant. But this is the narrowest possible view. When we include a broader horizon and consider either the public interest of the colony itself, or that still larger public interest which is represented by the advance of scientific medicine, we find abundant cause for regret. The short facts are that the population of Jamaica is too sparse and poor over a large portion of the island to support a sufficient number of medical men. To meet this evil the Government has divided the country into medical districts, and, by means of subventions, has provided in every district the means of living for a local medical man. This practitioner has received an official appointment to which a small salary has been attached, confessedly by way of a retainer, his official duties being originally very light, and his principal task that of building up a private practice in the common interest of himself and the population specially confided to his care. These official duties have, however, grown gradually more and more onerous; and quite recently, in connexion with a reform of the Poor Law, the Legislature has cast so much unremunerated work upon the hands of its district medical officers as to threaten seriously to interfere with their private practice. It is abundantly plain that such a policy, both by its direct and its indirect effects, can only injure the Jamaican community. Even the work of poor relief, when arbitrarily and unjustly imposed upon unwilling hands, is apt, we fear, to be grudgingly performed. Still that, no doubt, will be done. What is far more serious is that the work of tending the sick who are not also indigent must be more or less neglected. The philanthropic work of ministering to the wants of the "disinherited" is of itself a noble task, and one eminently fit to be the care of Government and singularly congenial to professors of the healing art. But it is obvious that in a country circumstanced as is Jamaica there are claims paramount even to those of the sick pauper class—the claims, namely, of the sick, without distinction of social status. In sacrificing these larger claims to the smaller the Legislature of Jamaica is, in our judgment, committing a grave mistake, which we trust they will have the wisdom to discover and the candour to acknowledge in the practical way of rectification.

Of the injustice involved in the casting of public burdens on to the shoulders of one class we do not speak at length. The point is too plain to need elucidation, and where the sources of indignation lie so near the surface it is pleasanter at least, perhaps even safer, to pass with a light and hurrying tread. We rather choose to remark, in conclusion, that the indirect loss to Jamaica of the more capable men whom a liberal policy would attract to her shores is a heavy price to pay for the petrifogging economies of the new Poor Law. Isolated and daily face to face with grave medical problems, the district medical practitioner, to

Digitized by Google

be fully equal to his responsibilities, should be chosen from among the most accomplished of his class. To such the field for practical and scientific achievement is illimitable. But opportunities are thrown away upon inferior men, and from this class the medical staff of Jamaica will assuredly be recruited unless by a return to more liberal and more equitable administration the Colonial Government succeeds in re-establishing good relations with the local medical profession.

Annotations.

"Ne quid nimis."

THE LATE MR. RICHARD QUAIN AND UNIVERSITY COLLEGE.

THE late eminent surgeon by his will, dated Aug. 5th, 1887, has bequeathed almost the whole of his fortune, amounting to about £75,000, to University College, London, subject to certain annuities to family connexions. The trustees—Lord Justice Fry, Sir William Jenner, the Warden of Merton, and Sir George Young—"are to apply the annual income in the promotion and encouragement, in connexion with University College, London, of general education in modern languages (especially the English language and composition in that language) and in natural science." It has been suggested by contemporaries that this affords an excellent opportunity for endowing London with a Teaching University, but it is obvious that the testator intended his munificent gift for University College, and for that College only. A large discretion is given to the trustees, but there can be no doubt that the wishes of Mr. Quain will be scrupulously carried out; and his suggestions for the benefit of the teacher and the pupil, "paying those who teach by salaries or other payments, as by endowing professorships," and "by pecuniary aid to those who are being taught, as by endowing scholarships and fellowships," are sure to have precedence in consideration.

DISCUSSION ON BILIARY CALCULUS AT THE MEXICAN ACADEMY.

AT a recent session of the Mexican Academy of Medicine, Señor Lavista reported an operation which he had performed on a case of enlarged and suppurating gall-bladder containing a considerable quantity of biliary calculi. The opening was made parallel to the border of the ribs, at a distance of two centimetres below it. The gall-bladder was laid open after being stitched to the abdominal parietes. The walls were found to be coated by a pseudo-membranous deposit of fibrin, in which the calculi were encysted. The cavity was scraped out, and it was then found to present three diverticula, one directed downwards, one towards the epigastrium, and another backwards, extending as far as the posterior border of the liver. Through this last the inner surfaces of the ninth, tenth, and eleventh ribs could be easily reached. Two drainage tubes were inserted into the wound and antiseptic dressing applied. At another session of the Academy a discussion arose out of the papers of Señor Lavista and Dr. Morales Pereira (see THE LANCET, October 1st, 1887) regarding the medicinal treatment of gall-stones, which, according to the President, Dr. Soriano, is an affection peculiarly common in Mexico, and for which he had been in the habit of using Durand's mixture (sulphuric ether and turpentine), but for which *simonillo* and *doradilla* (cotaraoh) enjoyed a considerable reputation. Señor Penafiel said that he had had no experience of the plants mentioned, but that he had used another Mexican plant, the *Kalea sacachiche*, employed with great benefit in the case of an inhabitant of Pachuca who had suffered from biliary calculus. This drug had caused the expulsion of a large number of gall-stones and cured the patient completely. Dr. Soriano stated that a medical friend who suffered frequently from symptoms of hepatic calculi, which sometimes set up true hepatitis, having tried various methods of treatment, had latterly adopted that of the *simonillo*, which had caused him to pass several calculi, since which time he had been quite well. He had, however, continued to take the drug. On being interrogated as to the manner in which the *Kalea sacachiche* acted on the gall-stones, whether by disintegration or solution, Señor Penafiel replied that it was impossible to say, the patient had passed two or three tablespoonfuls of pear-shaped grains, which were red by transmitted light and violet by reflected light. After passing these the patient recovered completely, and had had no return. In another case he had seen, the calculi were large and cigar-shaped, and were passed during, and apparently on account of anæsthesia.

PROFESSOR VON LANGENBECK.

WE regret to record the death on the 30th ult., in the seventy-seventh year of his age, of the celebrated German surgeon, Professor von Langenbeck. The following is a brief summary of the career of our late illustrious *confrère*:—

Bernhard Rudolph Konrad von Langenbeck was born in 1810 at Horneburg. He studied at Göttingen, and graduated in 1835 with the dissertation, "De Retinæ Structuræ Penitiore." Soon after he published his essay on the "Origin of Venous Cancer and the Possibility of Transferring Cancer from Man to Animals." He then became Extraordinary Professor in Göttingen, and wrote an essay on "Persistent Spasm of the Fingers and the Application of Division of Muscle and Tendon in its Treatment." He then busied himself with the questions of "Stammering and the Employment of Myotomy in Defects of Speech arising from Spasm," and the "Immediate Union of Wounds by Exclusion of Air." In 1842 he became Professor of Surgery and Director of the Friedrichs Hospital. In 1848 he was Director-General of the army of the Duchies against Denmark; and in 1847, after Dieffenbach's death, he was appointed Director of the Clinical Institute for Surgery and Ophthalmic Surgery. Amongst other essays of minor importance are the following: "Subcutaneous Osteotomy"; "The Permanent Warm Water Bath in the Treatment of Large Wounds, especially of the Stumps after Amputation"; "On the Extirpation of Interstitial Uterine Fibroids"; "The Osteoplastic Resection of the Upper Jaw"; "Essays on the Surgical Pathology of Veins"; "On Cleft Palate"; "On Resection of the Ankle in Gunshot Wounds"; "On Gunshot Wounds of the Joints"; "On the Terminations of Resection Operations in War"; "On Extirpation of the Pharynx"; "On Gummatous Tumours." Professor Langenbeck has of late years lived in Wiesbaden.

SMOKE NUISANCE ABATEMENT.

COPIOUS details are given in the Chief Commissioner's Report of the work of the Metropolitan Police during 1886 under the Smoke Abatement Acts. The total number of cases in which proceedings have been taken has shown a gradual falling off for some years past, and the record of 1886 is marked by the same feature. This is probably in large measure due to the continually increasing use of smokeless fuel, such as gas and gas coke, or of hydraulic power. In this way the progress of invention is doing much more to rid the metropolis of the nuisance of its smoke than the Abatement Acts. Indeed, it would seem as if these statutes, weak as they undoubtedly are, have never yet had a fair chance, for, again, the smallness and irregularity of the fines inflicted where convictions have been obtained are made the subject of remark by the Com-

Digitized by Google

missioners. The average fine was in 1886 smaller even than in the previous year, and amounted only to £1 17*s.* 5*d.* Even making a liberal allowance for costs, this does not seem to be a large price to pay for the privilege of persistently annoying a populous neighbourhood. It were much to be desired that the metropolitan magistrates took more to heart considerations of the public health. Bakers and confectioners are very useful people in their way, and deserving of all respect; but we are at a loss to understand why, when by outrageously unscientific methods of manufacture they bring themselves within the magisterial jurisdiction, they should be let off easily. No doubt their services are highly necessary to the public weal, and for that very reason they should be the more carefully taught to consider the public weal at every point in their operations.

INTESTINAL SURGERY.

A REMARKABLE paper on Intestinal Surgery was read at the General Surgical Section of the International Medical Congress at Washington on Sept. 5th by Dr. N. Senn, a synopsis of which is given on another page of our present issue. It is interesting to learn thus early a new method of dealing with perforating gunshot wounds of the intestine by omental grafting, with and without scarification of the serous surfaces. This he calls—(1) the "adhesion" experiment; (2) ileo-colostomy in intussusception or intestinal obstruction, by opening the bowel above and below and bringing the artificial openings in apposition with decalcified bone plates; (3) enterorrhaphy, or the rubber ring method without the omental flap, when excision of bowel is necessary for gangrene—as in hernia, for example. This mode of dealing with the bowel consists in bringing the healthy ends of the intestinal tube together by means of a circular india-rubber ferrule or tube, made easily out of a piece of thin Martin's rubber bandage about an inch long, inserted into each end of the bowel, and the serous surfaces sewn together round this tube on the outside. Dr. Senn claims for the operation that in dogs it is a matter of little consequence whether three inches or three feet of intestine are removed. His results have been obtained chiefly on dogs, and the specimens shewn at the Congress by him were, we are informed, handed over by him to Mr. H. W. Freeman of Bath, who has brought them with him to Europe. These specimens were procured from dogs killed at the end of a fortnight, and show a perfect union in each case. The omental grafting effectually prevents all escape from the intestine into the peritoneal cavity. After forty-eight hours' application the omentum is placed as a band around the gut that has been perforated, and the ends sewn together only to the mesentery. Mr. Freeman writes to us that he will be happy to show these specimens.

GOVERNMENT COPYRIGHT.

A TREASURY Minute has just been published defining the Government claim of copyright in official publications. The official view is that literary or *quasi*-literary matter—e.g., the reports of the *Challenger* expedition, the Rolls publications, and other similar works, also charts and Ordnance maps—should be made the subject of a Government monopoly of reproduction. The reasoning by which this conclusion is supported upon public grounds is interesting and specious, if not quite convincing. "Unless," say the Lords of the Treasury, "copyright is enforced, cheap copies of the works or of the popular portion of them, can be produced by private publishers, who reap the profit at the expense of the taxpayer. And as such works are in any case a burden on the taxpayer, the greater the burden the fewer works can the Government, with justice to the taxpayer, undertake." Whence the conclusion is drawn that in the case of works of this class copyright should be enforced "in the interests of the taxpayer and of literature and science." It may freely be admitted that as a mere matter of arithmetic the proposition thus generalised is unassailable. But the arithmetical view of this subject is a very incomplete one, and it will, we think, be a matter of much regret to all who have the interests of science at heart that this very mercenary view should have prevailed. The publication of the "most popular parts" of a scientific report means the publication of the short result and summary of the whole, and there can, we take it, be no question that in the interests of science such publications are greatly to be desired. If the authentic statement of a generally interesting fact is denied except on the condition of purchase with it of a mass of detail and of evidence which the majority of readers have neither time nor inclination to digest, the sure result will be that paraphrase will take the place of republication. In that case the Treasury will probably realise—well, just what it would have realised from the sale of the original work in any case; and science will lose the benefit of the accuracy in statement which is the very crown and efflorescence of scientific writing. While, therefore, the new system appears to us well calculated to sacrifice the benefits of unrestricted publication, it seems as ill-adapted to secure the pecuniary advantages which afford its theoretical justification. Even were this not so, we should feel bound to protest against the injury done to science by the adoption at the Treasury of the maxims of the shop; as it is, we feel that our protest need be guarded by no saving of the illusory interests of the taxpayer to which "my Lords" appeal.

PHYSIOLOGY OF SHORTHAND.

A PAPER on the Physiology of Shorthand Writing, by Dr. Gowers, excited considerable interest at the recent Shorthand Congress. Shorthand is only a variety of writing, and the paper was therefore mainly occupied with an account of the cerebral physiology of writing. The chief points in the physiology of the brain relating to the act of writing were first described. It was explained that the arm-centre of the cortex is merely concerned in producing the movements for the written symbols, and that the word-processes are arranged in the motor speech-centre on the left side, as is shown by the fact that disease of this centre abolishes the power of writing as well as of speech. Thus in the work of the reporter, as far as is at present known, there is no direct transfer of the nerve-processes from the auditory to the arm-centre; they must go through the motor speech-centre. The fact that it is the activity of the latter centre which excites the arm-centre and the movements for the written symbols, affords a strong theoretical justification for the phonetic element in shorthand, in which the written symbols are uniform for the same speech-processes. The non-phonetic systems, in so far as they do not adopt the phonetic principle, proceed on a resymbolising of the ordinary longhand signs; there are two steps to the process, whereas in the phonetic systems the symbols replace the longhand signs, and are placed at once on their permanent footing in direct relation to the speech-processes. No doubt, however, the practical difference is less than appears from theoretical considerations, because in all systems the shorthand symbols ultimately stand in very close relation to the word processes, and are produced without any consciousness of intermediate steps. It was pointed out that the term "phonography," applied to the "phonetic shorthand," is not strictly accurate, since it is the speech-process, and not the auditory impression, that immediately excites, and is symbolised by, the written sign. It is really "speech-writing," not "sound-writing." The error is not great, however, because the speech-process and

Digitized by Google

the auditory process are in perfect correspondence. The curious fact was mentioned that many persons, perhaps all persons, read by means of the motor speech-centre, so that if this is destroyed the power of reading is lost, and illiterate persons actually move the lips in reading. This affords another justification for the phonetic principle—i.e., for the uniformity of relation between the written symbols and the motor processes. The paper concluded with some remarks on the muscular mechanism of writing.

SMALL-POX AND VACCINATION.

MR. WILLIAM TEBB, well-known as an anti-vaccinationist, quotes, in a letter to *The Times*, a portion of an article which appeared in our columns over sixteen years ago, and uses it to help him in his argument that vaccination is no protection against small-pox. He refers to our statement that over 10,000 lives had, up to the date of our writing, been sacrificed in England and Wales to small-pox during the epidemic year of 1871, and that 73 per cent. of the admissions into London small-pox hospitals had been amongst vaccinated people. He refrains, however, from adding that our article showed also the exceptional virulence of small-pox on the revaccinated as compared with the vaccinated, [and he ignores the fact that a primary vaccination in infancy is not held to have the power to afford complete protection against small-pox in after years, and this especially when those who have failed to secure revaccination find themselves in the midst of an epidemic which is essentially due to failure to secure the full protection of vaccination. Whilst investigations during the past ten years into the influence of vaccination have shown that the protective effect wears off, they have also abundantly proved how potent is the protection of a comparatively recent vaccination against small-pox. Any tendency to numerical increase in small-pox cases is amongst the adult classes, whereas the vaccinated infantile community, which in non-vaccination days suffered most, is practically exempt from the disease. In short, revaccination is as necessary as primary vaccination. The facts brought forward in the report of the Medical Officer of the Local Government Board for 1881 are very conclusive on the point of the protective power of vaccination as regards children. Thus, it is shown that of 55,000 children under ten years of age who had not been vaccinated, 782 died from small-pox that year; whereas the deaths amongst 861,000 vaccinated children were only 125. And these 125 included vaccinations giving every variety of evidence of protection—good, bad, and indifferent. And it is clear that if the 861,000 vaccinated children had died at the same rate as the 55,000 unvaccinated, an additional 12,000 small-pox deaths of children under ten years of age would have occurred in the metropolis that year, and that the immense saving of life effected was due to vaccination and nothing else.

DEATH THROUGH EATING WHELKS.

THE adjourned inquest concerning the death of a soldier named Smith was concluded at Colchester on October 1st. Since the death of the deceased, some three weeks ago, a chemical analysis of the stomach has been made by Dr. Dupré. No traces of poison were discovered. The jury returned a verdict to the effect that death was due to some undetermined poison contained in the whelks eaten by the deceased. We have not been furnished with a complete account of the symptoms shown by the deceased during his fatal illness, but a full inquiry failed to reveal any other known cause of death. Of course, it is just possible that the ingestion of the whelks and the death were facts simply in sequence, and not related one to the other as cause and effect. At the same time, too many cases have been recorded to lead one to doubt that there is something more than a mere coincidence. It may be, and probably is so, that the poisonous matter is developed with great intensity in certain instances, but it is not unlikely that the susceptibility to the action of the poison is more marked in some individuals than in others. It has been truly said that what is one man's meat is another man's poison. A wide field is open for investigation into these enigmatical causes of death, for we know but little or nothing concerning them. To elucidate the nature of the poison contained in some molluscs, whether the result of an elaborating life process or of post-mortem decomposition, both chemical analysis and physiological experiments are required.

THE INTERNATIONAL HYGIENE CONGRESS AT VIENNA.

THE cause of hygiene throughout Europe must be advanced greatly by the Congress which has just been held at Vienna. Part of the opening remarks of the Crown Prince were admirable, including those memorable words, "Man is the most precious capital of the State and of society in general: every individual life represents a certain value." It is satisfactory, too, to notice the important part in the discussions taken by our countrymen Sir Spencer Wells, Dr. Humphry, Mr. Shirley Murphy, Dr. Corfield, and others. Not the least pleasant incident of the Congress was the distinguished honour done to Sir Spencer Wells by a special banquet in honour of him by the surgeons and professors of Austria-Hungary. The only toast was "The Guest of the evening," Professor Breisky doing full justice to Sir Spencer and the great operation with which his name will ever be inseparably associated, which has added lustre to surgery, and years to the average duration of life. Sir Spencer made a reply at once genial and able, acknowledging early lessons in the School of Vienna, and branching off vigorously into the great subject of hygiene, of which he has become one of the most lucid expounders. He repeated the remarkable statement which he made last year: that in the last fifty years, in the reign of our present Sovereign, the average duration of human life has increased nineteen years—that is, from thirty to forty-nine years,—and this with very imperfect sanitary laws.

BOTHRIOCEPHALUS LATUS AND PERNICIOUS ANÆMIA.

IT may be remembered that last year Professor Runeberg advanced the view that "pernicious anæmia"—in some cases at least—was dependent on the presence of the intestinal tapeworm—Bothriocephalus latus. His contention was supported by Dr. Reyhen and others, but strongly opposed by such notable authorities upon the disease as Professors Biermer, Quincke, and Immermann. A case which tends to support Runeberg's view has been recorded by Dr. Schapiro (in "Wratsch," cited in *Centralbl. f. Bacteriolog.*, ii., 12). A lad thirteen years of age came under treatment for intense anæmia of a progressive type, characterised by great diminution of red corpuscles (viz., to one-sixth of normal) and of hæmoglobin, with liability to cutaneous hæmorrhage, epistaxis &c., marked cardio-vascular bruits, pyrexia, and without any emaciation. It was not until the administration of anthelmintics had resulted in the evacuation of a large quantity of segments of bothriocephalus (to such an amount that several worms were probably present) that he began to regain strength and colour. His recovery from that date was rapid. The writer attributed the anæmia to the disintegrating action on blood-corpuscles of some chemical product of the parasite which was absorbed into the blood.

THE SCARLET FEVER EPIDEMIC.

IN the week ending October 1st no less than 318 fresh scarlet fever patients were admitted into the hospitals of the Metropolitan Asylums Board. There remained 69 vacant beds in the urban hospitals, and as soon as the pavilions at Winchmore Hill can be furnished 160 more convalescents can be removed to that institution; but this only offered a prospect of 229 more beds, and day by day that number is diminishing by reason of the large number of cases stil coming in. It must also be remembered that the number of discharges for some time to come will be small; for, out of 1586 scarlet fever cases under treatment up to October 1st no less than 1329 had been admitted within six weeks and 800 within three weeks. In view of the rapidly approaching emergency, the managers asked the Local Government Board if they knew of any institution that was available, but they have answered that no workhouse or infirmary could, to their knowledge, be obtained. Under these circumstances a committee has been appointed to do the best they can, and at the same time to make progress in the erection of huts on the open spaces available at the existing hospitals. Dr. Bridges, representing the Local Government Board, congratulated the managers on having taken up the question of providing for convalescents; and, adverting to the contention that patients were kept in too long, he declared that in his visits to the hospitals during the past two months he had not seen a single patient who could properly have been discharged. He then raised an important point by expressing a hope that the managers would face the fact that they were the isolation authority for the metropolis, and that they would extend the number of their beds from 2000 to 3000. This was in accordance with the recommendation of the Royal Commission on Fever Hospitals; but that Commission further added that a reconstitution of the Board was needed. It is not Poor-law work to protect the public against infection, whether the infected are in receipt of Poor-law relief or not. It is essentially sanitary work, and since it will be impossible ever to call upon some forty different sanitary authorities to act independently in this matter, the sooner the managers are converted into a sanitary body by the weeding-out of much of the Poor-law element the better it will be for the metropolis. Such an arrangement will also in the end conduce to economy; for, whilst the expense must in either case be borne by the ratepayers, it is notorious that action by multiple bodies is the most extravagant of procedures.

FIRES IN THEATRES.

PROFESSOR JOHN MARSHALL, in a thoughtful letter to *The Times*, suggests that by structural arrangement the dangers of fires in theatres could be in some degree lessened in so far as the audience is concerned, and this quite independently of "the uncertain action of temporary contrivances, of agitated managers, and of momentarily paralysed assistants." Professor Marshall points out that as theatres are at present constructed the draught of air is always from the stage to the windows above or behind the gallery, and that when a fire breaks out, which it usually does upon the stage, the gallery serves, as it were, as a chimney to the fireplace, and its occupants are stifled by the products of combustion. He suggests that theatres should be constructed so that the draught should be in the opposite direction—viz., from the auditorium to a covered outlet in the roof above the stage, which he assumes is generally the highest part of the house. The ceiling of the auditorium must in this case be apse-shaped, sloping from behind the gallery upwards to a series of valved outlets (to prevent back draughts) placed above the proscenium. Mr. Marshall would, in fact, arrange the ventilation of his house on the model of a hop or malt kiln. This suggestion seems to us to be excellent, not only because the outlet for foul air is placed in the proper situation, but also because such a construction necessitates inlets for fresh air in the auditorium—inlets which, as theatres are at present constructed, are generally non-existent. The ventilation of theatres is scandalously neglected, and its neglect is a standing reproach to the architectural profession, which is sorely in need of some method for ensuring that those admitted to it shall be masters of at least the rudiments of natural science. There must also be other means of making theatres less dangerous than they now are. Few of us would regret the absence of a mass of flimsy and tawdry decorations which disfigures many of our theatres, and certainly increases the risk of fire. Surely, also, a great deal of the scenery might be rendered incombustible. Tin plate is nowadays almost as cheap as canvas, and we should have thought that with a very ordinary amount of ingenuity it might be made a suitable medium for the scenic painters' art. The use of the electric light is a step in the right direction, but of itself it only helps to diminish risk, and does not abolish the necessity of observing other precautions.

ENEMA LESIONS.

DR. ACHILLES NORDMANN, of Basle, has published a description of twenty-five bowel lesions due to the operation of administering enemata. They include three complete perforations and ulcers, and wounds of various depths and sizes. The causes of these lesions seem to have been the use of defective instruments, ignorance of the direction of the rectum, catching of the transverse fold on the tube, extreme irritation of the mucous membrane of the bowel, and obstructions caused by certain conditions of the uterus, the fœtal head, or an enlarged prostate. As a rule, these lesions are to be found on the anterior wall of the rectum, from one to seven centimetres from the anus. They are not always easy to diagnose, as other foreign bodies or caustics may produce similar appearances. Tubercular and hæmorrhoidal ulcers may be mistaken for them; these are, however, generally higher up. A perforating wound gives rise to paraproctitis, but this is not necessarily fatal, though a stricture generally results.

CHOLERA INTELLIGENCE.

THERE is some evidence that cholera is diminishing in Sicily. No returns now come from anywhere but Messina, and even these are irregular. During the week ending the 3rd inst. 175 cases and 115 deaths were reported, but in two days no returns were made. In Naples cholera still continues to cause mortality, but there is no tendency to an increase of the disease. The same may be said of Rome, where the cases have been largely of the sporadic type. From Malta we learn that the epidemic gives indications of dying out, but there were twenty deaths during the eight days ending October 3rd.

THE FORESTERS AND CONVALESCENT HOMES.

OUR contemporary, the *Observer*, says that the Midland Counties Courts of the Foresters are about to erect a Convalescent Home for their members, to be self-supporting. We wish the scheme all success. Our contemporary, in a sanguine spirit, goes on to suggest that the Foresters should not stop at convalescent homes, but go on to build hospitals (and of course maintain them) with such help as might be expected from large City companies and wealthy firms, into which their members or their wives and children might go in time of sickness. We cannot go quite so far as our contemporary here. It is not clear that hospitals could be raised in any such way as this, and they would inevitably

Digitized by Google

compete with and damage the existing hospitals, which certainly need no competition, and which have open doors for all real cases, whether the patient be a Forester or an Odd Fellow, or neither one nor the other. For the really destitute the workhouse hospitals already provide, and our existing hospitals are for the benefit of the class best represented by our friendly societies. All that is wanted is that they should organise larger subscriptions to existing hospitals.

FRENCH MILITARY SURGEONS AND PROFESSORSHIPS.

A SURGEON-MAJOR in the French Army, who is also an *agrégé*, or assistant professor of anatomy, lecturing at Lyons, was recently appointed by the Minister of Public Instruction to a chair at Lille, vacant by the death of the former occupant. Three days after the announcement of this appointment in the official journal a notification appeared in the same journal signed by the Minister of War, stating that this gentleman was ordered to Tonquin. Here, therefore, we have an officer in the army, who is at the same time an official under the Minister of Public Instruction, ordered by his two chiefs to be in two distant places at once. It would seem to us an absurdity for a military surgeon to take an appointment as a civilian professor at a provincial medical school; but in France it is not impossible, though apparently the Minister of War objects to it, and has determined to make it impossible, in this particular case at least. In a somewhat polemical article on the subject, a writer in a French medical journal complains that scientific eminence is rather at a discount in the medical department of the army, where the efficiency of a medical officer is reckoned far more from the reports of the colonel under whom he serves than from the scientific work he has done. It is also remarked that the Corps de Santé does not now attract the *élite* of the medical schools, and that the class of those entering the service cannot be expected to improve while so little encouragement is given to those who are desirous of extending their professional acquirements. The author thinks that it should be recognised that there are in the army, as in civil life, two classes of doctors, one suited for constant practice, the other susceptible of a higher degree of scientific culture. Let the first class be left with their regiments, and give the others the hospitals, allowing them to compete for the coveted distinction of *agrégation*.

THE TIME OF COMMENCEMENT OF MENSTRUATION.

DR. SULLIES finds from inquiries made from 3000 pregnant women from the neighbourhood of Königsberg that menstruation commenced at the mean age of sixteen. The taller and the weaker girls menstruated earlier than the shorter and the stronger girls, and the brunettes earlier than the blondes. The earliest of all were the tall, weakly blondes; the latest, the short brunettes of medium strength. In 83 per cent. the function was performed regularly at the first.

THE ROYAL BERKSHIRE HOSPITAL.

A COMMUNICATION has been made to Mr. Benyon, the vice-patron and President of the Royal Berkshire Hospital at Reading, of which Her Majesty is patroness, expressing, on the part of twenty-eight medical men in active practice in Berkshire and the adjacent parts of Bucks, Hants, Oxfordshire, and Surrey, a desire to see a Fellow, or at least a Member, of the College of Physicians of London established in Reading as a consulting physician in connexion with the hospital, at which there is now a vacancy. It is also stated that a feeling exists among the above-mentioned gentlemen that reforms are needed at the Royal Berkshire Hospital, if it is desired that they should continue to advise their poorer patients to seek the aid of the hospital to which their richer patients are subscribers. The governing authority of the Reading Hospital can scarcely ignore such an expression of views.

HYSTERO-EPILEPSY CURED BY A SHAM OPERATION.

DR. CHIARLEONI, believing that the good effects said to be produced by spaying on women suffering from the different forms of hysteria are to a large extent attributable to the mental and moral impression produced by the operation, determined to put this theory to the proof on the next suitable patient who came to his clinic. This happened to be a woman who, after a fright, had been affected by hystero-epilepsy, with more or less convulsive and paralytic symptoms. There was evidently no disease of the pelvic organs. She was subjected to a pretended ovariotomy, which, however, was merely an incision into the abdominal parietes, but was accompanied by all the paraphernalia of a true abdominal section, chloroform being of course given. This operation was followed by a complete cure; consequently Dr. Chiarleoni thinks that spaying should not be resorted to except in cases in which it is imperatively necessary.

MYELITIS FROM A HYDATID TUMOUR.

A RARE case of myelitis due to compression by a hydatid tumour is reported by Dr. Pedkoff in the *Meditsinskoe Obozrênie*. The patient was a young woman who had for some time noticed a tumour on the left side of her back. At first it gave her no trouble but when she applied for advice there was decided loss of power in the lower extremities. Afterwards the temperature rose and arthritic symptoms began to appear, simulating those of acute rheumatism. Paralysis both of motion and sensation, together with retention of urine and obstinate constipation, supervened. The tumour was then opened; a quantity of colourless liquid first came out, followed by a number of hydatids. The wound was left open, and in the course of a month something like 100 hydatids must have come away. The patient gradually became weaker, and died. Unfortunately no post-mortem could be obtained.

MEDICAL RELIEF AND DISFRANCHISEMENT.

THE *Liverpool Courier* reports that in the Registration Court all cases of simply medical relief were allowed, but that in a case where the claimant had been for three weeks in Brownlow Hill Hospital suffering from rheumatism, the vote was disallowed. The Barrister thought the statute did not include hospital treatment, excepting cases where the local authority used the parish hospital for infectious cases, to which the patient went, not from poverty, but for the sanitary advantage of the public.

MEDICINE AND SURGERY IN ENGLAND.

THE *Graphic*, in its issue of the 1st inst., contains a lengthy and interesting account of the rise and progress of the art and science of medicine and surgery in England—in other words, a history of the Royal Colleges of Physicians and Surgeons. An account is given of the foundation of these Colleges, the connexion with and separation from the Barbers' Guild, their vicissitudes of fortune, culminating in one instance in bankruptcy, and their gradual progress to their present state of authority and importance. The sketch is profusely illustrated, among the most noteworthy of the appeals to the eye being portraits of Linacre, Cains, and Harvey, and sketches of the old building of the College of

Digitized by Google

Physicians in Warwick-lane (now demolished), and the Court Room of the Barbers' Hall in Monkwell-street. Our contemporary in the same number also publishes collections of pictorial representations of "An Ambulance Class of Ladies," and "The Career of a Naval Surgeon at the Royal College, Haslar."

WILLIAM HARVEY.

As our readers are doubtless aware, next year will be the 260th anniversary of the publication of Harvey's immortal treatise "Exercitatio Anatomica de Motu Cordis et Sanguinis." In anticipation of the interest which this event will awaken, Mr. Richards of Holborn Viaduct has secured the copyright of a statuette of the famous physician by C. B. Birch, A.R.A., the sculptor, which, reproduced in terra cotta, aids materially in the adornment of the room in which it is placed, and serves to keep green the memory of one to whom the medical profession is so much indebted.

GASEOUS RECTAL INJECTIONS AND THE GLYCOGENIC FUNCTION OF THE LIVER.

MM. ARNOZAN and FERRÉ of Bordeaux communicated to the Toulouse Congress an interesting observation they had made with reference to gaseous rectal injections tending to show that sulphuretted hydrogen introduced into the animal economy in this manner arrests the glycogenic function of the liver. Three rabbits which had been subjected to these injections died, two of them in a short time, the third after a rapid and progressive emaciation. In all three the liver tissue was found to contain no sugar whatever.

THE ADVANTAGES OF NOTIFICATION OF INFECTIOUS DISEASES.

MEASLES having become fatally prevalent in Newcastle-upon-Tyne, Mr. Henry Armstrong has advised the Town Council to take steps for the tentative notification of this disease under the special act in operation in the borough. Only some half a dozen authorities have included measles in the list of diseases to be notified; but as the disease is so largely spread through the agency of elementary schools, and since there are now improved facilities for controlling such spread by the aid of the regulations under the Education Code, there may well be substantial grounds for the advice given. In Warrington measles is now being notified as a temporary measure, and the proposal with regard to Newcastle is that it should, in the first instance, be a notifiable disease for a period of five years. In giving his advice, Mr. Armstrong has set out materials for judging of the value of notification generally. In Newcastle this system came into operation under an Act passed during 1882; and since that date there have been some remarkable reductions in the fatality from certain infectious diseases. Thus, during the four years 1883 to 1886 the small-pox deaths have been 60, 12, 3, and none respectively; the typhus deaths were 24, 6, 7, and none; continued fever, 7, 3, 4, and none; and scarlet fever, 124, 156, 83, and 45. But, ignoring the fact that there has been no similar reduction in the case of enteric fever and diphtheria, we almost fear the time is premature for drawing anything like a definite conclusion from these results. Small-pox and typhus have always been, of all diseases, most amenable to immediate notification if followed at once by isolation; but even typhus reappeared in Newcastle this year. And as to scarlet fever, we know how its epidemic prevalences run in cycles, and it is to be presumed that the time for the next increase has, as yet, not come for Newcastle. In 1881, without notification, the deaths from this disease were only 7 more than in 1886, but then came a sharp rise to 82, 124, and 156 in the three following years. We have no wish to imply that the admirable sanitary system organised in Newcastle will be unable, with the aid of notification, to cope with the next epidemic; but we cannot regard the experiment as having been continued for a sufficiently long time to have really proved that the reductions in mortality which have taken place are due to compulsory notification.

IS CANCER CONTAGIOUS?

M. DUPLOUY of Rochefort reports a case where a man, who had for a long time carefully nursed his wife, who was suffering from uterine cancer, became affected with epithelioma of the glans penis, necessitating amputation. The question arises, Is this a mere coincidence, or does it point to the possibility of cancer being transmitted by contagion?

THE MEDICAL SOCIETIES.

THE Clinical Society will hold its first meeting on Friday, Oct. 14th; the Pathological Society on Tuesday, Oct. 18th; the Ophthalmological Society on Thursday, Oct. 20th. The Obstetrical Society commenced on Wednesday last.

FROM the report of the results of analyses of the metropolitan water supply made by Dr. Frankland, and recently issued by the water examiner appointed under the Metropolis Water Act, 1871, it appears that during the month of August the Thames water distributed by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies was for river water exceptionally free from organic matter, the average proportion present being even less than in July. Of the water principally drawn from the river Lea, that supplied by the New River Company contained less organic matter than any of the other waters, excepting that of the Kent Company, whilst the East London Company's supply contained slightly more organic matter than the Thames waters. All the samples were clear and bright.

AT a debate which took place at the Oxford Local Board on Wednesday upon the report of Dr. Thorne Thorne and Mr. Gordon Smith relative to the sanitary condition of Oxford, and the comments which had been made thereon in the daily press, Mr. Omond, Bursar of St. John's College, moved the following resolution:—"That the board regrets that a memorandum conveying an erroneous impression of the matters in dispute should have been presented to the Local Government Board." After a short discussion the resolution was carried unanimously.

THE guardians of the parish of St. James, Westminster which is one of the parishes benefited by the Craven Charity, have applied to the hospitals which receive subscriptions from this fund to receive scarlet fever patients. Under the contract between the trustees of the Charity and the authorities of the hospitals, the latter can be compelled to take in a certain number of cases (infectious or otherwise, small-pox alone excepted), but this is the first occasion on which any demand has been made for the provision of acccommodation during an epidemic of fever.

THE inaugural address at the Midland Medical Society will be given by Dr. Sydney Ringer on Nov. 9th. The subject of the address will be, "The Antagonism of Drugs, and its bearing on the Administration of Medicine."

THE epidemic of diphtheria at Dorchester has assumed serious dimensions, and several deaths have occurred. Mr. Kendall, a highly respected practitioner, is lying seriously ill, having caught the infection whilst attending a patient.

Digitized by Google

MR. ALFRED EMSON, consulting-surgeon to the Dorset County Hospital, and one of the oldest practitioners in Dorset, died on the 5th inst. under melancholy circumstances. In February last, whilst performing an operation for cancer, Mr. Emson pricked his finger with one of his instruments. Blood poisoning set in, and, after months of suffering, death ensued from this cause. The deceased was seventy years old.

THE Cunard steamer *Aurania*, which arrived at Queenstown on the 2nd inst. from New York, brought details of the arrival at that city on the 22nd ult. of the Transatlantic liner *Alesia* from Marseilles with 364 passengers, sixteen of whom were then suffering from Asiatic cholera, eight others having died on the voyage and been buried at sea.

ON the 29th ult. the death occurred of Mr. Samuel Berry. The deceased, who retired from practice about five years ago, was formerly surgeon to the Queen's Hospital and Professor of Midwifery in the Queen's College, Birmingham. Mr. Berry was at the time of his decease in his eightieth year.

SIR GEORGE MACLEOD, M.D., Surgeon in Ordinary to the Queen in Scotland and Professor of Surgery in the University of Glasgow, has been appointed to succeed the late Dr. Fergus as Crown Representative for Scotland in the Medical Council. The appointment has our hearty approval.

THE Banbury Board of Guardians have resolved not to do their duty. By eighteen votes to ten they decided not to enforce compulsory vaccination. Are boards of guardians to make the laws of England? Or have they a discretionary power of throwing them into abeyance?

IN the Chancery Division, on the 5th inst., Mr. Justice Charles declined to grant an injunction restraining the Sheffield Corporation from erecting a small-pox convalescent hospital on some land situate near Totley Rise, Derbyshire, about five miles from Sheffield.

THE Lord Mayor for next year, Mr. Alderman Polydore De Keyser, is the grandson of a distinguished surgeon, and was himself intended for the same profession, an arrangement which was, however, set aside by the death of his brother in 1850.

THE death is announced of Dr. Lazarus Wittmann, *privat docent*, of Buda-Pesth.

THE ETIOLOGY AND TREATMENT OF SCARLATINA.

THE adjourned meeting of the Edinburgh Medico-Chirurgical Society for the discussion of the above subject was held on Wednesday evening, October 5th. The chair was occupied by Professor Grainger Stewart, President of the Society. Owing to the fact that the post-graduate courses are now in progress, there was a large attendance of visitors from a distance, in addition to the members of the Society. The President having opened the meeting, and referred to the discussion which took place in July, of which the present proceedings were the continuation, called upon Mr. A. W. Hare to read a second report now presented by the committee appointed to investigate and report upon the recent Edinburgh Researches into the Etiology of Scarlatina. The text of the report is as follows:—

SECOND INTERIM REPORT BY COMMITTEE.

Since submitting to the Society the preliminary report, your committee have further prosecuted the investigation of facts relating to Mr. Edington's paper on the Nature of the Contagium of Scarlet Fever. The committee have now collected a considerable amount of evidence bearing on the several points under consideration. While, however, the facts before them are of considerable importance, they do not as yet feel themselves in a position to present a final report. The following is a summary of their work:—

1. *Microscopical examination of the blood.*—Blood from ten typical cases of scarlatina, on or before the third day of the disease, was examined microscopically for the presence of micro-organisms. In this part of the investigations forty-four specimens were examined under the microscope, with the result that in the blood of one patient bacilli and micrococci were found, both in small numbers; in that of two patients bacilli and micrococci were found, the former in very small, the latter in moderate numbers; in that of four patients micrococci alone were found; and in the remaining three cases no micro-organisms could be detected.

2. *Cultivation experiments with the blood.*—The blood was taken from nine typical cases of the disease on or before the third day. In four of these cases bacilli and micrococci appeared in the culture material; in two micrococci alone; and in three a negative result was obtained. It is worthy of notice that the cases in which microscopic observation failed to discover micro-organisms only in one instance corresponded with those in which cultivation experiment failed. So that, taking the nineteen observations together, evidence of the existence of organisms was obtained in thirteen; or, taking the series of ten cases to which those observations refer, evidence of a positive nature was obtained in nine of them. The committee are not yet in a position to describe all these forms of microbes, but they are at present engaged in the investigation of the nature of the several organisms.

3. *Cultivation experiments with desquamation.* — One typical case was examined with negative results.

4. Several experiments were performed on calves with the "bacillus scarlatinæ" supplied by Mr. Edington. These consisted of an inoculation experiment by subcutaneous injection and scarification with this material, a feeding experiment with the same, and a combined feeding and inoculation experiment. In each case the result was negative.

5. In conjunction with Professor MacFadyean of the Royal Dick Veterinary College, to whom the thanks of the committee are due, three experiments were performed in which it was attempted to induce scarlatina in calves by injecting scarlatinal blood in two cases, and by feeding with desquamated scales in the third. The materials were from typical cases of the disease. These experiments also gave negative results.

6. The committee feel waranted in expressing their belief that the "bacillus scarlatinæ" of Edington is not, as suggested by some observers, the bacillus in eczema (Smith), the bacillus butyris, or the bacillus subtilis. They have, however, not yet been able to compare it with certain other forms of bacillus which it is said to resemble—*e.g.*, the bacillus epidermidis, the bacillus of acute rheumatism (Mantle), and the bacillus found in the skin in erythema marginatum (Mantle).

7. They believe that they have definitely ascertained the fact that the micro-organism described by Mr. Edington under the name of "streptococcus rubiginosus," is morphologically identical with the "streptococcus scarlatinæ" of Dr. Klein. The value of this identification is emphasised by the facts as to inoculation experiments described by Mr. Edington in a letter appended to this report.

In conclusion, your committee beg to state: (1) That they find that an organism resembling that described by Mr. Edington as "bacillus scarlatinæ" is in a certain proportion of cases present in the blood taken with due precautions from scarlatinal patients. (2) That they believe that the streptococcus scarlatinæ of Klein is identical with the streptococcus rubiginosus of Edington. (3) That they have as yet failed to corroborate the conclusions arrived at by Mr. Edington as to the pathogenetic value of the bacillus scarlatinæ.

The committee desire to obtain the sanction of the Society to continue the investigation, particularly as regards (*a*) the morphology of the several organisms; (*b*) the susceptibility of various animals to infection with scarlatinal blood and with the various organisms; their investigations so far

Digitized by Google

having led them to doubt whether calves are susceptible to the action of human scarlatinal poison. They have therefore to ask the sanction of the Society for such further expenditure as this fresh line of experimentation may demand. Subjoined is a letter, with enclosure, which has been received from Mr. Edington, to which reference was made in the report and which the committee deem of such importance as to place before the Society *in extenso*.

ARTHUR W. HARE.

ADDENDUM.

[COPY.]

41, Great King-street, Edinburgh, October 3rd, 1887.

DEAR SIR,—I herewith send you a letter received by me from Dr. Boswell Park, M.D., Professor of Surgery, Medical Department, University of Buffalo, together with microscopic preparations which accompanied it. The letter fully explains what they purport to be. Having carefully examined them, I am unable to see any distinctive difference in them from the bacillus which I have described, but I have intimated to him that these preparations of themselves are not sufficient to enable me to say that they are the same. You will, however, note that he states that cultivations in different media correspond with those described by me.

In response to your question as to my experimentation in man with scarlatinal material, I beg to say that, having inoculated a tube of gelatine with scarlatinal blood of the fourth day, I was successful, after thirty-six hours' incubation, in getting a profuse cultivation of streptococcus rubiginosus and diplococcus scarlatinæ sanguinis; and, having emptied half of it into some fresh milk, it was drunk by my brother. Three days later his blood, on being examined, showed micrococci, which, being cultivated, showed that the streptococcus rubiginosus was present. His temperature was carefully taken morning and evening for fourteen days, but never showed the slightest pyrexial rise. I might also state that he never has had scarlet fever. From this fact I doubt very much the pathogenicity of this organism in man.

I am, dear Sir,
Yours respectfully,
(Signed) ALEXANDER EDINGTON.

Professor Grainger Stewart, M.D., Convener of Medico-Chirurgical Society's Committee for the Investigation of the "Bacillus scarlatinæ," &c.

[COPY.] Buffalo, Aug. 24th, 1887.

DEAR SIR,—We have been very much interested in your papers on the Bacillus scarlatinæ, in Nos. 1380 and 1388 of the *British Medical Journal*, especially so because we have for the past fifteen months been cultivating a bacillus which seems to correspond with the one described by you. It was taken from the blood of a case of scarlatina when the eruption was well marked by puncturing the skin under due antiseptic precautions. It has been cultivated on gelatine, agar-agar, and potato, with the same characteristic growth detailed in your articles, and has seemed to be a comparatively pure culture from the start. Just now we have a beautiful potato cultivation undergoing the changes of colour you describe. The mounted specimens accompanying this letter were taken from it on the fifth and sixth days respectively. We have had no time to make inoculation experiments, or to study the bacillus carefully, and we are anxious to know whether it really corresponds to the bacillus found by you.

Respectfully yours,
(Signed) BOSWELL PARK, M.D.,
Prof. of Surgery, Med. Dept., University of Buffalo.
Alexander Edington, M.B., C.M.

THE NATIONAL SOCIETY FOR AID TO SICK AND WOUNDED IN WAR (British Red Cross Society) has received from His Highness the Khedive of Egypt Bronze Stars in favour of the following gentlemen for their services, under the auspices of the Society, in aid of the sick and wounded in the Egyptian Campaign 1884-5-6:—Egypt: Commissioner John Smith Young, and Surgeon Edward Francis White. Soudan: Commissioner Sir V. H. B. Kennett Barrington, and Commissioner Sir Allen Young; Surgeons Chas. H. Newby, J. Edward Squire, F. C. H. Piggott, and Richard Lake; Professor Alexander Ogston.

HOSPITAL RÉUNIONS.

CHARING-CROSS HOSPITAL.

THE annual dinner of the past and present students of the above institution will take place on Friday, Oct. 14th, at the Holborn Restaurant, at 7.30 P.M. Chairman: A. Julius Pollock, Esq., M.D., F.R.C.P.

KING'S COLLEGE HOSPITAL.

THE old students' dinner took place at Limmer's Hotel on the 4th inst., at 7 P.M. W. Paul Swain, Esq., F.R.C.S., was in the chair, and he was supported by a large number of the medical staff and about eighty former students. The principal toast—"King's College and King's College Hospital"—was proposed by the Chairman and drunk with great enthusiasm. His student days under Fergusson, Budd, Todd, and Partridge were very feelingly referred to, as well as their successors—Beale, Henry Smith, and Wood,—who then held junior appointments. Dr. Wace, the Principal of King's College and the chairman of the Committee of Management of the hospital, in replying, pointed out that recently great changes in the sanitary arrangements of the hospital had been made, and that a new nursing school had been instituted. Surgeon-Major Partridge replied for the Services, whilst Dr. Playne, of Maidenhead, and Dr. Buzzard responded for country and town friends respectively. A very enjoyable evening was spent, and Dr. Hayes and Mr. Rose, the honorary secretaries, were congratulated on its success.

LONDON HOSPITAL.

THIS dinner was held in the New Library of the Medical College, and an opportunity was thus given to a large number of old London Hospital men to inspect the very handsome buildings that have taken the place of the old College. The chair was taken by Sir Andrew Clark, Bart. Nearly 200 friends and old students of the Hospital were present, and among them were the members of the medical staff, the lecturers at the College, the members of the College Board, and the chairman (Mr. Carr-Gomm) and the treasurer (Mr. T. H. Buxton) of the hospital. The guests included Deputy Surgeon-General Harris, Surgeon-Major Poole, Dr. Glover, Dr. Christie of Ealing, Dr. Robert Barnes, and others. Sir Andrew Clark, in proposing the toast of the evening, gave an account of the history of the College from its commencement, and of its remarkable development during the last few years. Mr. Treves proposed the toast of "The Army and Navy," Mr. Buxton and Mr. Corner those of the "Medical Staff" and of "The Hospital." Dr. Stephen Mackenzie, to whose energies the success of the dinner was largely due, proposed the toast of "The Old Students." Among the other speakers were Mr. Carr-Gomm, Mr. Couper, Dr. Sansom, Mr. Munro Scott, and Mr. Openshaw.

The band of the Coldstream Guards played a selection of music in the gallery during the evening.

ST. MARY'S HOSPITAL.

A DINNER was held on October 3rd in the grand hall of the Criterion, Mr. George P. Field, Dean of the Medical School, in the chair. Considerably over two hundred gentlemen were present, including Dr. Chambers, Dr. Downes, Dr. Lawrence, Professor J. E. Morgan, Dr. J. D. Maurice, Dr. Milner Moore, Surgeon-Major Myers, Dr. Platt, Dr. Owen Roberts, Mr. Spencer Smith, Dr. Danford Thomas, Surgeon-Major H. de Tatham, Mr. Worth, Dr. Handfield Jones, F.R.S., Sir Edward Sieveking, Dr. Broadbent, Dr. Cheadle, Dr. Leeb, Dr. Braxton Hicks, F.R.S., Mr. Norton, Mr. Page, Mr. Malcolm Morris, &c. The usual loyal and patriotic toasts were given by the Chairman. In proposing the toast of "Success to St. Mary's Hospital Medical School," Mr. Field referred to the prosperous condition of the school and the steady progress it had made; the new entries, which for 1883 numbered thirty, had, during the four succeeding years, followed the satisfactory gradation of forty, fifty, sixty, and seventy, irrespectively of many students who had entered for special

Digitized by Google

classes and short courses. Mr. Field stated that the negotiations for the acquisition of property adjacent to the hospital were actively progressing, his remarks as to the probable early extension of the hospital into Praed-street being received with enthusiastic acclamation. The toast of "Past and Present Students of St. Mary's Hospital" was given by Dr. Braxton Hicks, and on behalf of past students was responded to in most felicitous terms by Professor Morgan of Manchester. Other toasts were given, and a highly successful gathering was brought to a close by the recitation of "Horatius" by Mr. William Terriss.

MIDDLESEX HOSPITAL.

IN the evening of Oct. 3rd, after the distribution of prizes at the hospital, a large number of past and present students dined together at the Holborn Restaurant, under the presidency of Mr. T. W. Nunn. After dinner the usual toasts were drunk, and speeches were made by Mr. Nunn, Major Ross, M.P., Brigade Surgeon Cayley, Surgeon-Major Hopkins, Mr. Morris, Mr. Lowne, Dr. Fowler, Mr. Hulke, Dr. Alderson, Mr. Vickery, Mr. Burdett, Mr. Wylde, Mr. Ganz, Mr. Smith Turner, and the Dean. Very excellent music was contributed by Mr. Ganz, Dr. Pringle, and Mr. Balfe. A message of greeting was sent from those present to Mr. Shaw, the only remaining member of the original teaching staff of 1835.

ST. THOMAS'S HOSPITAL.

ON the afternoon of Saturday the 1st inst., at 3 P.M., the usual inaugural address was delivered in one of the operating theatres of the hospital. The lecturer this year was Mr. R. W. Reid, Vice-Dean of the School and Lecturer on Anatomy. The theatre was crowded. The address (an abstract of which we publish at page 713) was listened to with much attention, only interrupted by frequent expressions of approbation on the part of the students. On the termination of the address there was a meeting of the staff, visitors, and students in the library. At 6.30 in the evening the annual dinner was held in the Governors' Hall, when about 120 past and present students assembled. The chair was taken by Sir W. Mac Cormac, and a most enjoyable evening was spent. After the usual loyal toast, the Chairman proposed "The Navy, Army and Reserve Forces"; this was responded to by Sir J. Watt Reid, K.C.B., for the Navy, and Sir Thomas Crawford, K.C.B., for the Army. Dr. John Harley proposed "The Visitors," which was replied to by Sir Henry Doulton, who referred to the unchecked advertising and large sale of infallible cures. Sir W. Mac Cormac proposed "The Health of St. Thomas's Hospital," to which Mr. Alderman Stone, the treasurer, replied, mentioning the mutual respect and friendship which existed between the medical staff and the governors. Sir John Simon, K.C.B., consulting surgeon to the hospital, proposed "The Health of the Chairman" with much feeling and eloquence, and Sir William Mac Cormac suitably replied. In the absence of Mr. Le Gros Clark, Dr. Alfred Carpenter proposed "The Medical School," and Mr. R. W. Reid responded. Dr. Stone, in a humorous speech, proposed "The Old Students," and Dr. Rosser (of Croydon) and Mr. Cresswell Rich (of Liverpool) replied; Dr. Bristowe, in the absence of Professor C. Stewart, proposed "The Secretaries" (Dr. Mackenzie and Mr. Battle), who briefly responded. During the dinner the band of the Coldstream Guards played a selection of music, which added much to the enjoyment of the evening. After the dinner songs were given by Mr. Caldicott and Mr. J. E. Nichol.

WESTMINSTER HOSPITAL MEDICAL CLUB.

THE annual dinner of the Westminster Hospital Medical Club was held on Monday, the 3rd inst., at the Holborn Restaurant, Mr. George Cowell, F.R.C.S., in the chair. Amongst those present were Sir Rutherford Alcock, K.C.B., Sir James Crichton Browne, Mr. Macnamara, Dr. Allchin, Dr. Sturges, Mr. Holthouse. Dr. Fincham, Dr. Donkin, Dr. Hall, Dr. Hughes Bennett, Mr. Cooke, Mr. Bond, Mr. Black, Dr. Sutherland, Mr. Quennell, and others, upwards of eighty having accepted. At this hospital, the staff and lecturers dine together every quarter and discuss subjects relating to the medical school, an example which might well be followed by other teaching bodies. A special tribute of praise was paid by the Chairman to Mr. Quennell, the indefatigable secretary of the hospital, for his courtesy and energy in carrying out the erection of the various grand stands to view the Jubilee procession, which brought in a large sum to the funds of the institution.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5475 births and 3097 deaths were registered during the week ending October 1st. The annual rate of mortality in these towns, which had steadily declined in the preceding seven weeks from 23·7 to 16·2, rose again last week to 17·5. During the thirteen weeks ending on 1st inst., the death-rate in these towns averaged 20·4 per 1000, and was 0·5 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 12·8 in Brighton, 14·8 in Portsmouth, 14·9 in Plymouth, and 15·4 in London. The rates in the other towns ranged upwards to 24·5 in Manchester, 25·7 in Halifax, 25·9 in Blackburn, and 31·6 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding nine weeks from 1301 to 440, rose again last week to 460; they included 168 from diarrhœa, 86 from scarlet fever, 62 from "fever" (principally enteric), 58 from whooping-cough, 39 from measles, 36 from diphtheria, and 11 from small-pox. These zymotic diseases caused the lowest death-rates last week in Sunderland, and Birkenhead; and the highest rates in Wolverhampton, Norwich, Preston, and Blackburn. The greatest mortality from diarrhœa was recorded in Cardiff, Wolverhampton, Norwich, and Blackburn; scarlet fever in Manchester, Oldham, Blackburn, and Preston; measles in Cardiff and Derby; and "fever" in Preston, Norwich, Leicester, Wolverhampton, and Salford. The 26 deaths from diphtheria in the twenty-eight towns included 20 in London, 3 in Huddersfield, and 2 in Newcastle-upon-Tyne. Small-pox caused 10 deaths in Sheffield and 1 in Bristol, but not one in Greater London or in any of the twenty-five other large towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; whereas the number of cases of scarlet fever in the Metropolitan Asylums Board hospitals and in the London Fever Hospital had increased to 1716. The deaths referred to diseases of the respiratory organs in London, which had been 142 and 160 in the preceding two weeks, further rose last week to 219, and were 1 below the corrected average. The causes of 81, or 2·6 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Sunderland, Nottingham, and in five other smaller towns. The largest proportions of uncertified deaths were recorded in Blackburn, Halifax, and Brighton.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·4, 18·7, and 18·3 per 1000 in the preceding three weeks, further declined to 17·7 in the week ending October 1st; this rate exceeded, however, by 0·2 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 3·2 and 16·4 in Perth and Greenock, to 20·9 in Leith and 24·8 in Paisley. The 442 deaths in the eight towns last week showed a further decline of 15 from recently weekly numbers, and included 23 which were referred to whooping-cough, 17 to diarrhœa, 12 to scarlet fever, 11 to "fever" (typhus, enteric, or simple), 6 to diphtheria, and not one to small-pox; in all, 71 deaths resulted from these principal zymotic diseases, against 112, 106, and 78 in the preceding three weeks. These 71 deaths were equal to an annual rate of 2·8 per 1000, which exceeded by 0·2 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 40, 19, and 22 in the previous three weeks, rose again last week to 23, of which 8 occurred in Glasgow, 5 in Dundee, 5 in Greenock, and 4 in Aberdeen. The 17 deaths attributed to diarrhœa showed a further considerable decline from the numbers in recent weeks; they included 5 in Dundee, 4 in Edinburgh, 3 in Aberdeen, and

Digitized by Google

3 in Leith. The deaths from scarlet fever, which had been 17 and 11 in the previous two weeks, rose again last week to 12, of which 7 occurred in Dundee and 4 in Glasgow. The 11 deaths referred to "fever" corresponded with the number in the previous week; and included 5 in Glasgow, 2 in Dundee, and 2 in Leith. Of the 6 deaths from diphtheria, an increase of one upon the number in the previous week, 3 were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 77 and 62 in the preceding two weeks, rose last week to 83, and exceeded by 16 the number returned in the corresponding week of last year. The causes of 54, or more than 12 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 34·3 and 30·6 per 1000 in the preceding two weeks, was 30·9 in the week ending October 1st. During the thirteen weeks ending the 1st inst. the death-rate in the city averaged 31·0 per 1000, the mean rate during the same period being but 19·6 in London and 18·2 in Edinburgh. The 209 deaths in Dublin last week showed an increase of 2 upon the number in the previous week; they included 19 which were referred to diarrhœa, 13 to measles, 3 to whooping-cough, 1 to "fever" (typhus, enteric, or simple), 1 to scarlet fever, and not one either to small-pox or diphtheria. Thus the deaths resulting from these principal zymotic diseases, which had been 52 in each of the preceding two weeks, declined last week to 37; they were equal to an annual rate of 5·5 per 1000, the rate from the same diseases being but 2·1 in London and 1·4 in Edinburgh. The fatal cases of diarrhœa, which had been 35 and 37 in the previous two weeks, declined last week to 19, but were still considerably above the average for the season. The 13 deaths from measles exceeded the numbers in recent weeks, whereas those from scarlet fever showed a decline. The deaths of infants exceeded by 16, while those of elderly persons were fewer by 6 than the numbers in the previous week. Five inquest cases and 2 deaths from violence were registered; and 65, or nearly a third, of the deaths occurred in public institutions. The causes of 34, or more than 16 per cent. of the deaths registered during the week were not certified.

SMALL-POX MORTALITY IN THE GERMAN EMPIRE IN 1886.

A report on the mortality of small-pox in the German Empire in 1886 has recently been issued in Berlin, bearing the name of Dr. Rahts. It is shown that among the more than forty-seven millions of the population of the German Empire only 155 deaths from small-pox were registered during last year, being equal to a death-rate of 3·3 per million. In England and Wales, with a population of rather less than twenty-eight millions, the small-pox deaths last year were 275, equal to a rate of 9·9 per million. Of the 155 deaths from small-pox in the German Empire, 61 were of infants under one year of age, 14 of children aged between one year and five years, 16 of young persons aged between five and twenty years, and 64 were of adults aged upwards of twenty years. A table in the report gives an interesting comparison of the death-rates from small-pox in 1886 in the largest towns of several European States. In 193 towns of the German Empire the death-rate from small-pox last year was 4 per million living; in twenty-eight English towns it was 8 per million (not 77, as misprinted in the report); in seventy-one Belgium towns it was 194; in fifteen Swiss towns it was 218; in forty-nine Austrian towns it was 325; and in twelve Hungarian towns it was 2428 per million. There is good ground for believing that these small-pox rates bear a very definite relation to the efficiency of the regulations for securing general infant vaccination in the different countries. During 1886 no death from small-pox was recorded in Breslau, Dresden, Cologne, or Frankfort, and only one in Berlin; while the highest rates in the large German cities were 30 and 36 per million in Konigsburg and Hamburg. Among the principal European cities outside the German Empire the small-pox rate per million ranged from 6 in London, 49 in Liverpool, and 90 in Paris, to 1213 in Rheims, 1342 in Rome, 1538 in Geneva, 3687 in Buda-Pesth, and 5453 in Marseilles. It is evident that both England and Germany enjoyed in 1886 a comparative immunity from fatal small-pox, which affords a striking contrast to the mortality from the disease in France, Austria, and Italy.

Correspondence.

"Audi alteram partem."

"PROTECTIVE POWER OF VACCINATION."

To the Editors of THE LANCET.

SIRS,—In the letter you honoured me by publishing in your last week's journal (p. 681) I had written that men "require a theory as an aid in further work or as a goal or object *for it*"—instead of "first." Overleaf, in the fifth line, a note of interrogation, followed by a capital, cuts a sentence into two parts where only a comma was intended. May I ask for space to correct these points, and again to repeat that M. Pasteur's new theory needs for its confirmation the experiments suggested by Mr. Vincent Richards. This inquiry could not be entrusted to better hands than those of the accomplished secretary to the Hydrophobia Commission. When he returns from his well-merited and happy holiday, we may hope he will be induced to undertake it.

I am, Sirs, yours very truly,

Oct. 1st, 1887. WILLIAM SQUIRE, M.D.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to correct an erroneous statement in Dr. Squire's letter, in your impression of the 1st inst., with regard to my predecessor Mr. Marson's practice as to the vaccination of the nurses and servants at this hospital. His usual custom was to vaccinate the nurses as soon as possible *after* their arrival at the institution, and preferably from arm to arm, either at the vaccination station here or at Blackfriars, and they were then sent on duty. The same practice has been continued at this hospital since Mr. Marson's resignation ten years ago, with equally good results. The disasters which occurred occasionally in the early days of the Asylums Board hospitals were, I venture to think, due to the use of lymph of a more or less inert character. When the medical officer of a small-pox hospital has any doubt as to the protective power of the vaccine lymph he is using, then certainly it is desirable that he should wait and ascertain the results of his vaccination before exposing his *employés* to the risk of infection.

I am, Sirs, yours faithfully,

HERBERT GOUDE, M.D.

Small-pox and Vaccination Hospital, Holloway, N., Oct. 5th, 1887.

To the Editors of THE LANCET.

SIRS,—Dr. Squire is mistaken in supposing that I questioned the experience that he referred to in regard to the protective power of vaccination after the infection of small-pox. I merely wrote for information, and gladly welcome any facts bearing upon the subject. I have not been able as yet to lay my hands on the London Asylums Board's Hospital Reports, but if the cases mentioned by Dr. Squire are all that are to be found there, few will think them sufficient to upset the whole former views, or to warrant the conclusion that vaccination under the circumstances is wholly useless. I do not suppose anyone says that vaccination will infallibly prevent small-pox if practised however early after infection, and it must be accounted rash to expose a person only just vaccinated to the infection of small-pox. But of its power to modify small-pox if practised early after infection, the facts are so numerous in its favour that it would take a great many adverse cases to subvert our faith in it. Much, I have no doubt, must depend upon the manner in which the vaccination is done, and the quality and quantity of the vaccine inserted.

I am, Sirs, yours faithfully,

Glasgow, Oct. 4th. HUGH THOMSON, M.D.

To the Editors of THE LANCET.

SIRS,—Permit me to comment upon Dr. Squire's letter on the above subject, which appears in this week's LANCET. Dr. Squire is correct in saying that the late Mr. Marson never received anyone for duty in the wards of the Small-pox Hospital "immediately upon vaccination, but waited for the result to be evident"; and, further, that he favoured

Digitized by Google

"the practice of vaccinating all in any house or room where small-pox happened." Dr. Squire, however, is, I believe, mistaken in supposing that Mr. Marson held that this latter operation secured complete immunity from the disease. I was an intimate friend and pupil of Mr. Marson, and know that from conviction he taught that vaccination would not procure immunity if the poison of small-pox had already gained admission to the system; he held that it might modify the intensity of the attack, but would not prevent it. This has always occurred to me as a difficulty in accepting Pasteur's plan of inoculation after a patient has been bitten by a rabid animal; and I cannot but think that Marson's experience of vaccination in small-pox militates against the adoption of Pasteur's views on the efficacy of inoculation after the introduction of the poison.

I remain, Sirs, your obedient servant,

Parkhurst-road, N., Oct. 1st, 1887. W. HENRY KESTEVEN.

SCARLET FEVER: PROPHYLAXIS AND TREATMENT.

To the Editors of THE LANCET.

SIRS,—The present epidemic of scarlet fever, which seems to be spreading over the country, induces me to ask you to allow me to bring before the profession generally a method of treatment which, in my hands, has proved an unqualified success, not only in overcoming the disease and in preventing those numerous sequelæ which are often more disastrous in their results than the disease itself, but, when applied to those who have not "incubated" the disease, acts as a remarkable prophylactic.

It is now some years since I first commenced to treat scarlet fever with carbolic acid. At first it did not appear to have any specially beneficent action, and my patients dying in about the same ratio as before, I gave up the use of it, returning to the old methods of treatment. After some little time, however, I returned to it, bringing more thought to bear upon the matter, being also more enlightened concerning the life of bacteria in general when placed under conditions which, if not inimical to life itself, at any rate had the effect of checking propagation and accepting as a foundation for treatment that the poison of scarlet fever was but the presence within the system of some, as yet unknown, species of bacteria, its severity being due to circumstances especially favouring development. I therefore commenced anew the administration of carbolic acid, with this difference, that the dose was considerably increased and its frequency doubled. The result, since I arrived at definite conclusions concerning the dose and its frequency, has been that even during severe epidemics I have never lost a patient, though I have treated now nearly 300 cases. Out of this number I have had but three cases of albuminuria, one of glandular suppuration; but no aural or nasal complications, no secondary fever or cardiac disease, and a rapid recovery from even severe cases that I have never before witnessed. I use liquid carbolic acid, specially prepared for internal use, and rendered liquid by the addition of 10 per cent. of water. In children from two to six years of age I order three minims in syrup of orange-peel and water, together about an ounce, and this must be given every two hours night and day for the first three days, longer if necessary, but if the patient is doing well, every three hours until the fourth or fifth day, then every four hours until all danger has past, and finally three times a day until perfectly convalescent. In older patients the dose should be four minims, and in adults even five or six. I have found eight minims (equal to over seven grains of pure carbolic acid) the maximum dose. Beyond that I should hesitate to push it, as at that dose nausea, griping, and diarrhœa result. Naturally, with an increased dose the menstruum must be proportionately increased, so as to do away with the rather hot acrid taste of the acid. It is, however, a matter of the utmost necessity that in the early stages the dose should be every two hours night and day, and the patient, if asleep, awakened to take it. It is in the frequency as well as in the dose that safety is found. Carbolic acid when introduced into the system is extremely "fugitive," entering into combination with wellnigh everything that it comes into contact with; hence the absolute necessity for its persistent frequent administration. An almost infallible test as to whether the dose and its frequency have been duly observed is to be found in the urine; in fact, I might also add whether the dose is sufficient. In the course of from twenty-four to thirty-six hours the urine begins to present a smoky hue, somewhat similar to that observed at the commencement of hæmaturia, and in time becomes almost black. The absence of this hue invariably indicates either that the frequency of administration has been curtailed or that the dose is not sufficiently large. I have never known it absent if even the dose has only been two minims, provided it has been administered every two hours. I never consider my patient safe until this peculiar hue is present, the deeper the better. That this peculiarity of the urinary secretion is not due to the blood I have practically demonstrated. It is, I am of opinion, the result of some peculiar combination of the carbolic acid with the products of renal excretion; for the urine is sometimes passed quite clear, but in the course of a short time assumes the characteristic hue. I consider this colour of the urine of the utmost importance, as only upon its appearance can we assume that the drug is thoroughly saturating the whole system; for so rapid is its excretion that when the carbolic acid is ordered to be given only every four hours, the tint disappears.

This, then, is the treatment that has proved so successful in my hands. But to be effective it must be commenced *ab initio*. It will not do to begin on the second or third day, and if failure ensue credit it to the treatment, though possibly even then it may prove better than the old system. I do not interfere with the ulcerated tonsils, which, so far as my experience goes, are invariably affected in scarlet fever. I look upon the extent of the ulceration as an indication of the severity of the attack, and increase the dose of the acid. Once only have I applied nitrate of silver solution, and this was in a strumous child where the whole of the fauces was coated in twenty-four hours with a diphtheritic exudation. The child recovered, but had glandular suppuration on both sides of the neck: the only case I have had. With reference to the three cases of albuminuria, all were clearly traceable to distinct causes. One patient ran out into the garden without a cap chasing a cat which had escaped from the nursery, a keen east wind prevailing at the time. A second sat before a broken window; whilst the third was similarly circumstanced. All these were sufficiently well to sit up, and in each case albuminuria occurred before the tenth day. All recovered.

Desquamation, as a rule, is neither so prolonged or so acute. I have had no occasion to again resort to cold baths to check excessive temperature, the highest record being 104·5°. Only twice have I had serious nervous disturbance, which was speedily subdued by large doses of bromide of potassium.

With reference to the administration of carbolic acid as a prophylactic, I have used it with the happiest results. I give to all the other inmates of the house who have never had scarlet fever, irrespective of age, one minim of the liquid carbolic acid three times a day, and I do not prohibit intercourse with the sick. The result has been that in a few instances—I think four—the disease has been taken but very slightly, whilst the large majority have escaped. That this immunity was due to the acid may be inferred because subsequently those exposed have been attacked severely but have recovered. In one case a second child was attacked five weeks after the first was well. The house had been disinfected by the municipal authorities. It was taken ill on a Friday with diarrhœa and vomiting, but being subject to bilious attacks little notice was taken of it; on Saturday it was dull and listless; it was seen at 7 o'clock on Sunday morning, and found in a state of collapse, and died five hours after from suppressed scarlet fever. Nevertheless, during the illness of the first child it was an inmate of the sick-room after the fourth day, but was preserved from attack by the daily doses of carbolic acid.

These few outlines I have hastily put together, and neither time nor space can be found to give details of the cases treated, interesting as they are. I would conclude therefore with these few words. Each case must be treated on its own merits. The treatment should be commenced the same hour that the case is diagnosed. The severer the case at its outset, the larger the dose. Well diluted and flavoured with tincture of orange-peel, the taste is not unpleasant. Extreme nervous excitement should be calmed with bromide of potassium, and extreme nervous depression with brandy and the usual adjuncts. Dismiss the idea that any harm can ensue from these doses of carbolic acid, but, when possible, patients should be seen at least twice a

Digitized by Google

day, to either increase or lessen the dose. If these views are carried out, the danger of scarlet fever will be reduced to a minimum, and those troublesome sequelæ, the dread hitherto of the practitioner, will rarely make their appearance.

I am, Sirs, yours, &c.,

ARTHUR WIGLESWORTH, L.R.C.P.L., &c.

Liverpool, Sept. 1887.

"THE DURATION OF SCARLET FEVER INFECTION."

To the Editors of THE LANCET.

SIRS,—Your annotation under the above heading in THE LANCET of Oct. 1st calls attention to a subject of great practical importance. The almost universally received opinion is that the infection lasts as long as desquamation continues, and that isolation of the patient is therefore necessary until the completion of that process. No doubt this was the correct and necessary practice in times past, but I question its necessity where the practice of disinfecting the patient's skin is thoroughly carried out. Unquestionably, the desquamating cuticle retains the infection longer than perhaps any other part of the body, but I have for a long time felt that if the skin is thoroughly anointed with carbolised or other disinfecting oil from an early period of the disease, and a daily bath containing some disinfectant be given as soon as the patient's condition will allow, he may with perfect safety be permitted to mix with others, even while peeling is actively going on. Acting on this belief, I have for some time back been in the habit of shortening the period of isolation without any evil result; and if this practice should, by a more extended experience, prove to be safe, the present congested condition of the hospitals of the Metropolitan Asylums Board might be much relieved.

I am, Sirs, yours faithfully,

Ludlow, Oct. 1st, 1887. MARK LONG, M.D.

JAMBUL IN DIABETES.

To the Editors of THE LANCET.

SIRS,—Since the publication of an abstract of my lectures on New Drugs in THE LANCET of Sept. 24th I have had many inquiries relative to my experience of jambul in diabetes. Would you permit me to answer them briefly in your columns?

First and foremost, the reason why I did not include jambul in my series was, not that I had found it *useless*, but that I was at the time of lecturing still accumulating results before pronouncing a definite opinion upon the drug. My experience is limited to surgical cases seen at the London and St. Peter's Hospital. They are as follows.

Diabetes insipidus.—No diminution of the urine with jambul.

Diabetes mellitus.—Cases presenting themselves with sloughing ulcers of diabetic origin, or accidental wounds in diabetics, refusing to heal under any application or treatment, gave these results: Water diminished; sugar decreased; ulcers filling in and wounds granulating and healing with surprising rapidity. Dose, 2½ gr. to 5 gr. in pearles thrice a day after food.

One case in point may be mentioned. A diabetic of eighteen months' standing, who had been lately under strict diabetic regimen and treatment, applied to me for relief of rapidly increasing sloughy ulcers of leg and thigh. These ulcers caused great pain. The patient stated that he filled a full-sized zinc pail with urine every night, and although he did not measure his urine in the day, he believed it was even greater in quantity. In one week with jambul (2½ gr. thrice daily) the urine diminished to one-half the quantity, and some of the deepest ulcers had filled up and skinned over. Few cases have impressed me so much with the value of jambul in diabetic ulceration as this.

I would seize this opportunity of saying that the New Therapeutical Society will be doing invaluable work if it devote some of its attention to the careful investigation and honest criticism of new drugs and remedies. Systematic and collective experience from the London hospitals alone would suffice in a few weeks to indicate worth, and to detect and reject much of the trash which is to be found in the mass of new remedies at present before the profession.

I remain, Sirs, yours truly,

Old Burlington-street. E. HURRY FENWICK.

"GAMALIEL IN WHITEHALL."

To the Editors of THE LANCET.

SIRS,—I have read your article of last week on Mr. Sclater-Booth's (I beg Lord Basing's pardon—"the king can do no wrong") invitation to the medical profession to disband themselves and to mistrust one another while trying to combat disease and death. You mention, without comment, Lord Basing's sneer at "Gamaliel in Whitehall." May I point out that a Hampshire squire might have read his Scriptures to the extent of learning what Gamaliel's teaching really was: "Let them alone," he says of those expounding truths which were new and possibly inconvenient to himself; "for if this counsel or this work be of men, it will come to nought; but if it be of God, ye cannot overthrow it." This would look like sensible advice—proceeding, indeed, upon the very lines that are commonly followed by the medical profession. It seems also to have come from a man who knew how to value facts above opinions, not from one who sought to decry advancing knowledge under cover of a hearsay phrase. I could wish it had been Lord Gamaliel who addressed the Sanitary Institute.

I am, Sirs, your obedient servant,

Oct. 3rd, 1887. WHITEHALL.

HEMIPLEGIA DURING THE PUERPERIUM.

To the Editors of THE LANCET.

SIRS,—In a conversation to-day with Dr. Finlayson regarding the case of hemiplegia during the puerperium, which is reported in the present issue of THE LANCET, he informed me that two apparently similar cases—that is of puerperal cerebral embolism without cardiac valvular disease—had been reported by himself. I find, on turning to the *Obstetrical Journal*, vol. vii., p. 666, that this is so, and that I have been wrong in supposing that my case was the first of the kind reported. Apart from the desire to correct this mistake, I am anxious, by referring to these cases of Dr. Finlayson's, to draw the attention of obstetricians further to this affection, which seems more common than is generally supposed; and it would be interesting to know to what extent such cases have occurred in the experience of your readers, or in the experience of others whose records they may have seen.

I am, Sirs, yours faithfully,

Newton-terrace, Glasgow, Oct. 1st, 1887. SAMUEL SLOAN.

ACCOMMODATION FOR INFECTIOUS CASES: A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—While there are to-day only eight beds in the fever hospitals available to meet the present epidemic, there are literally hundreds of beds standing empty at the general hospitals—two hundred at Guy's alone. If Guy's, for instance, would contract with the Asylums Board to take the enteric cases, that would relieve about a hundred beds. It would be thought undesirable to admit scarlet fever to special wards in general hospitals, but two of those with beds closed might combine, and, putting all their cases in one hospital, let the other to the Asylums Board. Anything is better than leaving the cases in their own homes, putting the unfortunate children in draughty sheds in November, or sending out the convalescents before they cease to be dangerous.

I am, Sirs, yours &c.,

October 6th, 1887. X. Y. Z.

THE DRAINAGE OF BEXLEY HEATH.

To the Editors of THE LANCET.

SIRS,—A short time ago I came to this healthily situated place, and was surprised to see how sickly the children and people looked after seeing those at Putney, the place I had been living in. I now attribute it to the want of drainage. Here is a place of several thousand inhabitants using cesspools which drain through the soil into one another: the old garden closets would be perfect safety in comparison. Close to me there is a valley, and in its sides are seen the blackish leakage ultimately on its way to the Thames. Wells must also receive their share. The main drains of London are not far from us, and yet we will not

Digitized by Google

connect. Ought not places of large size be compelled to do so, or use garden closets? It is sad to see lovely Kent villages so polluted, and London children had better be kept there than sent near places of this kind for their health. The expense of clearing out cesspools is greater than the rates would be, so that only those who never empty theirs are money gainers by this dirty and dangerous system. Something in your journal might cause people here to make a stir or move the authorities to interfere on behalf of those who wish to breathe real air instead of that from hundreds of impure drain-holes. Will not the cholera, when it comes, seize upon places like this in preference to those where there is drainage or closets in the ground, with no water used? I am, Sirs, yours truly,

G. BLAKELEY, Commander R.N.

Bexley Heath, Kent, Oct. 3rd, 1887.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—It is proposed at our next Council meeting to take into consideration the Darlington scheme, which, if adopted by the central authority, will enable Boards of Guardians to fix and regulate as they choose the salaries of all their officers. As this is a matter which will seriously affect all Poor-law medical officers, it is absolutely necessary that they should be "up and doing," as no time must be lost, a memorial to the President of the Local Government Board having been sent by the Darlington guardians and a request from them to all Boards of Guardians throughout the country to do the same.

Hoping to receive communications upon the subject from all Poor-law medical officers,

I am, Sirs, yours truly,

J. WICKHAM BARNES.

3, Bolt-court, Fleet-street, London, Oct. 5th, 1887.

THE SIXTH INTERNATIONAL CONGRESS OF HYGIENE.

(From our Special Correspondent.)

Vienna, Oct. 2nd.

THE greatest International Congress of Hygiene that has ever been held has now completed its labours. It is somewhat too early to judge the wisdom of its resolutions; and, indeed, these are buried in such a maze of documents, reports, and speeches that no one has yet fully realised what has been done. It is impossible to be in all Sections at one and the same time; and, were this even possible, the confusion of languages often makes it difficult to follow the debates. In this respect the Congress has not been so well managed as its predecessors. In all former congresses French was recognised as the official language. Speeches in other languages were allowed, but on the condition that they were translated into French, and, of course, all resolutions and official documents were drawn up in French, and the votes taken in French. Thus, foreign delegates were kept together and were fully able to follow the proceedings.

Considering the immense preponderance of Austrian delegates and members present, some regulation should have been established on the present occasian to prevent their speaking too often. The Germans, who, as the nearest neighbours, were the next in numbers present, joined heartily with the Austrians in speaking German. Thus speech after speech was pronounced in German, a language which the great majority of the foreign delegates present could not understand. These were so badly translated that the foreigners soon ceased asking for such interpretations; and, in some Sections, no attempt whatsoever was made at translation. Therefore the majority of the foreign members were obliged to pass wearisome hours, without understanding a word of what had been said. The result was that after a little of this experience a great many went away. Vienna is an attractive town; there were many excursions organised, and the proportion of foreign delegates at the Congress became less and less numerous. Instead of sitting out all the meeting, and taking an active part in the debates, they would look in for a moment or two and then revert to the greater attractions of the Ringstrasse. For hours together I was the only Englishman present in the several Sections I attended. Thus the Congress, to a considerable extent, degenerated from an International Congress into an Austro-German Congress.

Even worse than this was the method of voting. Those present raised their hands for or against the various proposition without any attempt to analyse the vote and ascertain what it represented. Thus, on one occasion, in the First Section, the Baron de Suzor and myself were the only persons present to speak or vote for Russia and England. If we take the Indian Empire, the English colonies, and the Asiatic as well as the European dominions of Russia, it will be found that the interests of something like five hundred million souls only counted as two voices in a division against thirty or forty Viennese doctors, who at most represented one single town. Considering that any Austrian who chose to pay 16*s.* was admitted as a member of the Congress, it was preposterous to give to hundreds of unknown amateurs who have never studied hygiene the same voting power as the distiuguished representatives of foreign governments and scientific societies. A national local congress could have told us what several hundred Viennese doctors have to say on various sanitary subjects. It was not necessary to bring delegates from all parts of the world to know what opinions prevailed at Vienna. What is wanted is the opinion of various nationalities on subjects of international interest. It would be most useful to record from time to time how this opinion develops itself; but if mere local majorities are to govern the decision of these congresses, there will be no sequence—they will alter according to each place where the congress meets, and will always exhibit contradiction. Thus, in Portugal the immense majority would be in favour of quarantines, and in England the result of the vote would be just the opposite. Evidently it is by nationalities that the vote should be taken. We want to know what nations are in favour of or against quarantines &c. The Austrians present should have had but one vote (however numerous they might have been), the Germans one vote, and so on for all nations. It is quite easy to call on the representatives of each nation to stand up and give their vote separately, and, when not agreed among themselves, the majority would govern, note being taken whether the vote was unanimous or not. The majority thus obtained would represent the opinion of the Congress—that is to say, a truly international opinion, and not, as at present, an Austrian vote with just a slight sprinkling of foreign elements. The as yet somewhat incomplete list printed sets forth that there were 2414 members of the Congress, and out of this number 1277 are marked as present. Now, of these members present, no less than 397 live in Vienna, and this does not include those who reside in the suburbs of Vienna. Thus, Vienna alone represents something like forty times the voting power of the entire British empire.

These criticisms are all the more necessary and important, as it is now decided, in response to an invitation of the British Sanitary Institute and the Association of the Medical Officers of Health, that the next International Congress of Hygiene shall be held in London. As the Universal Exhibition will draw most persons to Paris in 1889, it would be difficult to hold a Congress elsewhere that year; but, on the other hand, Paris has already been the seat of one Congress—namely, the Second International Congress of Hygiene. Consequently there will be a French Congress held in Paris in 1889, at which foreign representatives will not be obliged to attend, but where they will no doubt be heartily welcome if they choose to go. The Seventh International Congress of Hygiene will then follow in due course two years later—that is to say, in 1891,—and in London. In the meanwhile a committee has been elected to organise and prepare the International Congress, consisting of Dr. Brouardel for France, Dr. Dobroslavine for Russia, Dr. Billings for America, Professor F. de Gruber for Austria, Dr. Roth for Germany, Dr. Mosso for Italy, and Professor Corfield and Mr. Shirley Murphy for England. These gentlemen have agreed to meet at Dresden on the 10th of October next year to talk the matter over, and it is to be hoped that some arrangement will then be made to confer on the next Congress a more truly international and representative character.

In all other respects the present Congress has been a marvellous success. It would be difficult to find in all Europe a town better suited for a Congress than Vienna. The majesty of the buildings, the broad expanse of the thoroughfares, the splendid halls, restaurants, and meeting places all

Digitized by Google

combine to facilitate a brilliant reception; but, more than all, the innate amiability, the courtesy, the easy gracefulness of deportment which distinguish the Viennese population, make it alike a pleasure and an honour to be entertained by such a people. From the Crown Prince, who graciously received the members of the Congress at the Imperial Court, mixing and conversing freely with his guests, down to the humblest attendant at the University where the Congress met, all were alike animated with that spirit of amiability which leaves a lasting and most pleasant impression. The excursions to Semmering, to Kaiserbrunnen, and to many other places of interest near Vienna, were all admirably organised and successfully conducted. And now 400 members of the Congress start for Buda-Pesth in a special steamer, where they will be entertained for two days and shown many things of interest.

As for the actual work done by the Congress, the report of the speeches will fill more than one bulky volume. Nor is it easy to give the resolutions, for in some instances, instead of resolutions, the summary of long papers was adopted. These constitute little pamphlets of themselves; and if a Congress chooses to adopt a pamphlet instead of a resolution, it can scarcely expect the press to reproduce the pamphlet. This and other similar mistakes can only be attributed to the fact that a considerable proportion of the members belonged to countries where the freedom of meeting, of association, and of debate is to a great extent denied. They have not acquired the habit of self-government, and therefore do not know how to conduct meetings so as to produce the greatest influence on public authorities and on public opinion. While in some Sections the resolutions, or conclusions as they were sometimes called, were of impracticable length, in other Sections no resolutions whatever were put or discussed. Thus in Section 1, dealing with the question most germane to hygiene—viz., drainage,—no definite result was obtained. M. Durand Claye, the chief engineer of the Paris Ponts et Chaussées, presented a report on the Shone and Waring systems of drainage. It would be impossible to underrate the services rendered by M. Durant Claye. His energy is indefatigable. In all the Congresses he comes to preach the holy doctrine of cleanliness, of plenty of water, and plenty of air. In Paris, he has had the courage to attack vested interests, to defend poor and unprotected tenants in working-class districts against the sanitary delinquencies of jerry builders and rack-renters. But, in discussing the Shone system, he clearly showed that he knew but little about the subject. He objected to all separate systems, because the rain water washing down the gutter in the streets of towns contained as much organic matter and germ life as sewage itself. But, as M. Poutzen, who defended the Waring system, replied, it is not the quantity but the character of the germ which is of importance; and, as the germ of typhoid fever does not liquefy gelatine, its presence would not be shown in the analysis brought forward by M. Durand Claye. Many eminent sanitarians took part in the debate, and the opinion with regard to a separate system or canalisation for sewage proper was about evenly divided. With regard to the Shone system, it was pointed out that it was not necessarily a separate system. In the Houses of Commons it drained off the rain, and the rain occasionally amounted to forty times in volume the quantity of sewage proper. At Eastbourne, where the rainfall had recently been estimated at half an inch within an hour and a half, it also took all the rain-water. Nor was there any complicated machinery. The Shone apparatus for raising sewage to a higher level by pneumatic propulsion had been in work for six years at Eastbourne without any breakage, accident, or stoppage whatever occurring. The real question is that in many districts, localities, and towns there is not a sufficient fall for sewers. Hence the sewers are not self-cleansing. In many instances the sewers are much too large; there is therefore more room for the generation of sewer gas, and there are more deposits on the sides. Smaller sewers would be much cleaner; but, on the other hand, cause much more friction, and therefore require steeper gradients. These the topography of a town does not generally provide. They must be created artificially. When the sewage is too low down it must be lifted up, so that it may once more resume its course by the force of gravitation. Steam pumps, as a rule, take too much room, and are too expensive to be applied on a sufficiently extensive scale. It is in such cases that the Shone system, already employed in eighteen towns, renders great service. The case of Henley-on-Thames was cited, where, as compared with the expense of providing a steam-pump and ordinary sewers, an economy in the original outlay of 25 per cent. and in the yearly working expenses of 50 per cent. will be realised. At the same time the sewage will be lifted four times the height, thus giving the sewers a fall four times greater, and will be sent a mile further away from the town. In the face of these facts, M. Durand Claye, in his reply, withdrew his aspersions against the Shone system; maintained that the adoption of this or the Waring system must depend on local circumstances; and that, for his part, he was quite content if the Congress agreed with him in the necessity of doing away with cesspools, and of draining directly into the sewer. With concluding remarks to this effect the question was allowed to drop.

On the other hand, in the discussion on cholera and quarantine, an immense number of resolutions were brought forward, some containing very mischievous principles. But they were most ably combated by Professor Max Pettenkofer of Munich, Dr. Mosso of Turin, and Mr. Shirley Murphy of London. The latter gentleman pointed out that all speakers at the Congress had approved the necessity of enforcing sanitary reform in the towns exposed to infection. This was recognised on all sides as the most effective precaution. The only point under debate was whether such measures of medical inspection should be adopted as practically involved the imposition of a quarantine of five days. In England the belief in the utility of such a precaution had long since been abandoned. Its application would lead to the neglect of those sanitary measures so strongly recommended by Dr. Max Pettenkofer. The idea of excluding from Europe ships which, in passing the Suez Canal, were found to have had cholera cases on board was not logical, for the land route would still remain open. The retention of these ships would engender a sense of false security and prevent seaport and other towns adopting those sanitary measures which were really useful.

The manner in which these and similar observations were received showed how greatly public opinion has developed on this question; but the speech of Dr. Mosso, the Italian delegate, was particularly remarkable in this respect. He explained that Italy had gone through both experiences. They had imposed the strictest quarantine, and had imposed it everywhere. But it had proved to be good money thrown away. The same Minister (Signor Crispi) who had imposed quarantines now declared them to be useless. At Turin, thirty trains a day came to the town from an infected district during the recent Exhibition. There were about 100 cases of cholera imported, and no further mischief arose. Quarantine in the Red Sea, while Algeria, Tunis, and Tripoli remained open was a mere vexatious inconsistency. By far the greatest good would be done by telling people that their immunity from cholera depended on their using plenty of pure water and living in clean houses.

By such speeches the worst passages were eradicated from the resolutions; and when these are published they will show that opinion on the Continent on this subject has made considerable progress. The resolution will have issued from the printing offices in the course of a few days, and then, and in another letter, it will be possible to deal more fully with the work of the Congress.

BUDA-PESTH.

(From a Correspondent.)

SIR SPENCER WELLS and Professor HUMPHRY have just been here on their way to the Hygienic Congress at Vienna, which, as will be remembered, Sir Spencer was requested to attend as delegate by the College of Surgeons of England, and Professor Humphry by the University of Cambridge. The members of the medical profession of the place, being forewarned of the visit of Sir Spencer Wells, availed themselves of the opportunity to do him honour and pay him attention. At appointed times they met him at the several hospitals to show him the institutions and consult him respecting the cases. In the evening they gave him a banquet in the Queen of England Hotel, during which an address in English was made to him by the medical

Digitized by Google

students. In his reply, Sir Spencer encouraged them to diligent work, by which alone they could obtain success, and exhorted them to take advantage of the very great opportunities for clinical instruction which their hospitals afforded. Replying to his health, which was proposed in a complimentary English speech by Dr. Mackiesovszki, he thanked the members present sincerely for the honour they had done him, and expressed his great satisfaction at what he had seen in their hospitals. Professor Humphry, in reply to the toast, which was proposed to him as delegate from Cambridge by Dr. Jauffer, thanked those present on behalf of the medical profession in England for the honour they had done to one of its members who was justly esteemed for the part he had played in bringing about the great triumphs which had been recently achieved in abdominal surgery. The Professor further complimented them on their hospital arrangements, and the refinements in their instrumental methods of diagnosis, which exceeded, he believed, those employed in any hospital in his own country.

The hospitals which were visited certainly corroborate these remarks. Great attention is paid to ventilation and heating, which during the severe cold of winter are effected with much difficulty, to general sanitary arrangements, and to the care and comfort of the patients. The clinique of each professor occupies two or more hours daily. He attends himself to the dressings of the more important cases, and there is much harmony between him, his assistants, and the students. There is a physical laboratory, with a delicate electrical apparatus for testing the sensitiveness of the general surface and of the ear, the action of muscles, &c., in addition to the ordinary methods for diagnosis and treatment, also a histological and a bacteriological laboratory attached to each hospital. Antiseptics are largely used. In one ward under Dr. Ellescher were five women recovering from laparotomy on account of uterine and ovarian tumours. Several specimens of cancer of the uterus were shown, in which the whole organ had been successfully removed through the vagina by Dr. Jauffer, and this surgeon elicited the high approbation of Sir Spencer Wells for the manner in which he performed a difficult operation of enucleating from the left broad ligament a compound ovarian cyst of considerable size, which, from the position of the uterus and other signs, had been diagnosed by himself and Sir Spencer Wells to occupy that position. The carbolic spray was diffused through the room, not directed upon the patient, and carbolic water was freely used throughout. The bleeding vessels were secured with silk ligatures, and a portion of the broad ligament having been ligatured and cut away, the remainder was stitched to the surface of the uterus, as first done by Sir Spencer Wells.

The Red Cross Hospital, which has been opened about two years, receives private patients, who pay three, two, or one guilden (6*s*., 4*s*., or 2*s*.) a day, for which they receive board, lodging, and medical attendance, an extra fee being paid for operations. The plan and administration of this hospital are admirable. It is supported mainly by private contributions and subscriptions, and subsidised by Government, which pays for all the stores, medical and surgical appliances, ambulances and carriages for the sick and wounded, &c., which are kept here and supplied to the several military stations in time of peace, and to various parts in time of war. One block is reserved for nurses, who, having been trained in the hospital, are available for attending the surrounding district. The lady superintendent, who accompanied the party round, is a highly intelligent person, and deeply interested in the work, priding herself especially upon the excellence and cleanliness of the culinary department, as well as upon the variety of the stores and the manner of their disposition.

A NEW METROPOLITAN HOSPITAL. — The New Metropolitan Hospital buildings in Kingsland-road, which have for some time past been in course of erection, were opened for the reception of patients on the 1st inst. The institution was originally known as the Metropolitan Free Hospital, and has for some time had premises of a temporary character in Bishopsgate-street, but at a recent meeting of the governors it was decided that the word "Free" be omitted, and that in future all patients, except accidents, should contribute a small sum whilst under treatment. The cost of the new building, exclusive of the land, is about £25,000, but the entire cost when the intended south end block is erected is estimated at £40,000.

MANCHESTER.

(From our own Correspondent.)

OWENS COLLEGE.

THE opening of the medical department by an introductory address has within the past few years been more honoured in the breach than in the observance; this year, however, a return to the old custom is made, and Sir James Paget will to-morrow deliver the "introductory," which, from the high position held by Sir James as an orator, is being looked forward to by the profession with considerable interest. In the evening he will be entertained at the annual medical dinner to be held as usual at the Queen's Hotel. The departments of arts, science, and law were opened this morning by an address from Professor Dixon, F.R.S., successor to Sir Henry Roscoe in the chair of Chemistry. The evening classes of the College will be opened on Monday next by an address from Professor Kastner, and the department for women will be inaugurated by an address from the Bishop on the 17th inst.

ROYAL INFIRMARY, ETC.

At the last Board meeting of the infirmary an unusual offer was made to present to the institution a cottage hospital, to be situate in Hulme, fully furnished and equipped. The Board acknowledged the receipt of the handsome proposal, but requested time to consider the matter, as the maintenance of the hospital, some twenty beds in number, would entail an additional annual expenditure of at least £1000, and at the present time the Convalescent Hospital at Cheadle is a large drain upon the funds of the parent institution. At the same meeting Mr. Milner, late resident medical officer at Cheadle, was appointed resident surgical officer at the infirmary, in place of Mr. Collier, who has recently been appointed assistant surgeon to the Children's Hospital, Pendlebury. It is satisfactory to note that the higher resident appointments at the infirmary have of late been conferred upon Manchester students, as at one time it almost appeared that the powers that be had determined not to select students of our own school for the more responsible positions in the various institutions under their control.

HOSPITALS FOR INFECTIOUS DISEASES.

The question of the site for the new fever hospital proposed to be erected by the Salford Corporation is still a *quæstio vexata;* much angry discussion still goes on in relation to it, and much opposition will have to be overcome before the proposed building is an accomplished fact. At the last meeting of the Cheadle Local Board a proposal was brought forward for the provision of a small hospital there for infectious diseases, the cases from that district hitherto having to go to Stockport if they were isolated. At Newton Heath the Local Board still protest vigorously against the extensions of the Monsall Fever Hospital going on there, and consider they are hardly dealt with in having all the infectious disease of the city and suburbs brought into their township. At Gorton the Local Board have signified their willingness to pay 2*s*. 6*d*. for each certificate of infectious disease sent in by the medical practitioners of the district, compulsory notification not as yet being in force there.

POISONING AND HOMICIDE.

Two melancholy accidents have occurred within the last month at two of our hospitals. At the infirmary one of the house surgeons, in administering to himself a hypodermic injection of morphia to relieve the pain of neuralgia, took an over-dose, from which he never recovered; and at the asylum at Prestwich an attendant was attacked and killed by a lunatic, who had been an inmate for years and was considered quite harmless.

WATER SUPPLY.

Notwithstanding the late rainfall, we are still on "short time" with our water supply, it being turned off for twelve hours out of the twenty-four. The Water Committee assert that they are within three weeks of the end of their present supply, and that the rain hitherto has scarcely affected the quantity in the reservoirs; but now that the dry ground has become comparatively soaked, it is to be expected that each fall of rain will now find its way in large quantity to the reservoirs.

CHURCH PARADE.

The Manchester Division of the Volunteer Medical Staff Corps attended their first church parade at St. Matthew's Church on the 25th ult., when a special sermon was preached by Canon Kelly, honorary chaplain to the corps. At the review held on Saturday last by the Duke of Cambridge, the same corps marched out in most creditable style under the command of Surgeon Crockwell, and elicited some words of commendation from the Commander-in-Chief.

Oct. 4th.

LIVERPOOL.

(From our own Correspondent.)

SCARLATINA AT THE SCHOOL FOR THE DEAF AND DUMB.

IN consequence of a serious outbreak of scarlatina, the School for the Deaf and Dumb has been temporarily closed. Four cases were at once sent to the fever hospital of the workhouse, and subsequently six more. When Mr. Charles G. Lee, the surgeon to the institution, was first appointed some years ago, he found the sanitary arrangements most defective. At his suggestion most of these have been remedied, and little remains to be done to make the building as perfect in a sanitary sense as possible. This institution, which, though not a medical one, is of great interest to the profession, is under excellent management, and every opportunity is afforded to its afflicted inmates to receive a good education, and to be eventually enabled to earn their livelihood.

THE RECENT CASES OF HYDROPHOBIA.

As might have been expected, such an unusual occurrence as three fatal cases of hydrophobia occurring within so comparatively short a time, has produced a scare here. The order requiring all dogs in the street to be under control has been extended to all the neighbouring townships, and also to Bootle. No other cases have been reported.

THE MEDICAL FACULTY OF THE LIVERPOOL UNIVERSITY COLLEGE.

Dr. Campbell Brown, the Professor of Chemistry, having been for some time located in the new laboratories, those formerly occupied by him have been added to the physiological laboratories, where, under the able superintendence of Dr. Larkin, physiology is now learned by the students in a most thorough and practical manner. Many improvements have also been made in the dissecting and anatomical rooms, where students can learn anatomy with every comfort and convenience. The rooms will be reopened to-morrow, between fifty and sixty students have entered their names, and an ample supply of subjects has been secured.

THE ROYAL INFIRMARY.

The buildings are being rapidly taken down, and it is expected that the foundation stone of the new buildings will be laid on or about the 29th inst.

Liverpool, Oct. 4th.

BIRMINGHAM.

(From our own Correspondent.)

HOSPITAL SUNDAY.

A VIGOROUS appeal, signed by the Mayor and the secretaries of the Periodical Collections Committee, has just been issued. The proceeds this year fall by rotation to the Queen's Hospital, and the appeal sets forth in earnest terms the necessities of this deserving charity. When it is stated that the increase in the numbers over the last triennial period is over 28,000, and we learn that the estimated deficiency is £2500, it will be seen that there is a good case for urging the wants of the institution among the various places of worship in the town and district.

MUSHROOM POISONING.

A man, aged thirty-five, in apparently good health, partook of a hearty supper with a quantity of mushrooms. A few hours later he woke up complaining of abdominal pain, vomited, and became insensible, dying at 4 o'clock in the morning. The doctor who was called in attributed the death to blood-poisoning caused by the mushrooms, which were probably decomposed. He stated that he had lately seen a case where similar symptoms were produced by eating mushrooms, adding that some people were particularly liable to ill effects from eating them. It is of importance that to be wholesome they should be fresh, and free from any mixture with fungi of similar appearance but of poisonous properties. It is highly probable that Saturday night suppers are often eaten hastily and accompanied by much drinking; for example, at the same time, an inquest was held upon the body of a man who had died from choking, a piece of raw meat an ounce and a quarter in weight being extracted from his throat after death.

QUEEN'S COLLEGE.

The annual conversazione and distribution of prizes was held on the 3rd inst., and was largely attended. After the reception and address by the vice-president, Dr. Wade delivered an address, which was well received. The report stated that the number of entries at the commencement of last winter was 46, the number of students on the books of the College being 178; 36 passes had been obtained at the examination, 6 being at universities; at other examinations 98; making a total of 134. Since midsummer the intermediate examinations in medicine at the London University had been very successful with regard to this College, for of 7 who went up 5 passed in all the subjects. The year was also marked by the opening of the Eye Hospital and the Orthopædic Hospital to students for practice, which now took their place with the other hospitals and the Borough Lunatic Asylum for teaching purposes. The requirements of professional knowledge are thus amply rendered accessible to all who desire them.

CHURCH CONGRESS.

At the neighbouring town of Wolverhampton the assembly of the Church Congress excites a large and widespread interest. From a medical point of view the profession may be congratulated on the fact of the Mayor of Wolverhampton belonging to their ranks. The dignity of his office has been well represented in the reception given to the members of the Congress, and by the appropriate manner in which he has shown that the position of the two callings are united in the pursuit of the highest and best works.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NO AMBULANCE.

AN inquest has been held on the body of a miner who died in a few hours after admission to the Durham County Hospital, having been severely crushed by a fall of stone during his work; he sustained a fracture of the thigh and compound fracture of the left leg, and also fracture of the left arm. When admitted, the house surgeon, Dr. Collinson, found him in a state of collapse. It appeared that at the mine, there being no ambulance carriage at hand, he was placed on a stretcher in a coal cart, a mode of transit rather slow and rough for such injuries, the coal mine being several miles from the hospital. The coroner and the jury, however, seemed to think it a light matter, and that the unfortunate man had suffered no injury from the journey.

POPULAR LECTURES.

The season of popular lectures has set in here, and our professional brethren are well to the front in this matter, as they generally take up subjects which they well understand. Dr. Robertson of Newcastle gave an interesting and most instructive lecture last week on "Life in South Africa." Dr. Robertson was well qualified for the task; he possesses a full knowledge of the country from prolonged residence there, and it is no wonder that he was frequently applauded by a critical audience, who fully appreciated the abilities of the lecturer.

Newcastle-on-Tyne, Oct. 4th.

A YOUNG man has died at Hamilton from injuries received about a week previously while playing in a football match.

EDINBURGH.

(From our own Correspondent.)

THE SALUBRITY OF EDINBURGH.

THE water of Leith, a small tributary falling into the Firth of Forth, and traversing in its course some of the western districts of the city, has been for some years a source of annoyance and discomfort to the inhabitants of the localities through which it flows on account of its greatly polluted nature. This pollution has been shown by Professor Crum Brown and Mr. Reid to be in some part due to sewage contamination, but to a far greater degree traceable to waste products of manufactures finding their way into the river. It is alleged that this is especially true of the refuse material from paper works, where vegetable matter is allowed to ferment in water tanks to separate the fibrous constituents, just as is done in the preparation of flax. The water from these tanks, loaded with organic matter, and still in a putrescent condition, is allowed to enter the river in its higher reaches, and is by no means rendered pure and odourless before its flow through the city. Along its course the river deposits banks of mud, consisting chiefly of this organic matter originally in suspension in the water, and these mud banks left exposed in summer drought are a source of great annoyance. The Corporations of Edinburgh and Leith have at length, after repeated warnings, decided on taking legal measures conjointly for the abatement of the nuisance; and although this decision on their part has been met on that of the manufacturers by a strong protest in the form of a circular setting forth the "harassed and handicapped" condition of the British paper trade, it seems now certain that the matter will be pressed forward, and the nuisance, which has for long been a clamant evil, finally and completely removed.

THE WINTER SESSION.

The winter session will open two weeks hence, when a further advance in the number attending the University is expected. The preliminary examinations in general education now in progress are taken part in by nearly 400 candidates, an increase on the usual numbers at the autumn preliminary examination.

THE TEACHING OF AGRICULTURE.

Professor Wallace, of the Chair of Agriculture, is on his return voyage from India, whither he proceeded some months ago with the intention of becoming acquainted with the agricultural condition of that country. Every facility has been afforded him in his researches, and it is understood that his object has been fully realised. The materials now at his command will doubtless prove of much value in increasing the scope of his course of instruction, and enabling him to prepare students for a much wider area of usefulness than has previously been the case.

Edinburgh, Oct. 4th.

ABERDEEN.

(From our own Correspondent.)

ABERDEEN UNIVERSITY.

THE winter session commences on the 19th inst., and the preliminary examinations will be held on Monday, the 17th, and Tuesday, the 18th of October, commencing at 10 A.M. each day. A meeting of the General Council will be held in Marischal College on Wednesday, the 12th inst., and one of the items of business is a motion by Professor Struthers "that the Committee to watch over legislation affecting the University be reappointed." The office of Lord Rector of the University becomes vacant this year, and the Senatus have resolved to recommend to the University Court that Saturday, November 12th, be fixed as the most suitable day for the election of Lord Rector.

AMBULANCE LECTURES.

Mr. W. Leslie Mackenzie, M.A., lately delivered five lectures on Ambulance Work to railway servants. The lectures were illustrated by diagrams, apparatus, and specimens from the Surgical Museum, all placed at the disposal of the lecturer by Professor Ogston. The instruction was made as practical as possible. The attendance was very large, but divided into small classes. Each man had practical instruction in bandaging, the application of splints, &c. Mr. Dingwall, A.M., another medical student, delivered a similar course of lectures to the men engaged in one of our large quarries. Here also the instruction was as practical as possible, and the men entered into the work most enthusiastically. This work of ambulance instruction is carried on under the auspices of the Aberdeen Ambulance Association, and it is intended to hold classes during the winter in most of the large manufactories and works in the city.

Aberdeen, Oct. 4th.

DUBLIN.

(From our own Correspondent.)

KILKENNY.

SOME time since the services of Sir Charles Cameron as analyst for Kilkenny were discontinued, although his salary only amounted to £5 a year. At present there is a good deal of sickness in certain parts of the town, principally diarrhœa, which has been attributed to the water obtained from the pumps being contaminated with sewage. The Corporation are thinking of having the water analysed, and will have to pay a fee of two guineas for the same; while for the salary of £5 Sir Charles Cameron was bound to perform any number of analyses that might be required. Besides, it is not every medical practitioner who is sufficiently skilled in this particular branch to be able to analyse a sample of water, and it must not be forgotten that the cost of procuring the necessary instruments would amount to a very considerable sum. It follows from this, that should the Corporation require an analysis of the suspected water to be made, they may be obliged to obtain the services of Sir C. Cameron, the eminent analyst for Dublin.

THE DUBLIN DEATH-RATE.

The Public Health Committee of the Corporation of Dublin have had under consideration the excessive mortality in certain districts of the city, and have adopted the following resolution on the subject:—"That the attention of the dispensary doctors of Nos. 1, 2, and 3 North City, and Nos. 1, 2, and 3 South City, be directed to the very excessive death-rate in their districts, especially in No. 1 South City, where it reached 41·8, and in No. 2 South City, 52·24; and to request them to report if they can point out any cause for this excessive mortality, and whether it occurs in the infant or adult classes." The epidemic of measles, which has existed for months, during the last few weeks has shown a marked diminution in the mortality from this disorder.

The death is recorded of Dr. William Daxon, F.R.C.S., late resident medical superintendent of Ennis district lunatic asylum.

PARIS.

(From our Paris Correspondent.)

DR. BROUARDEL ON TYPHOID FEVER.

DR. BROUARDEL, who represented the French Faculty at the International Hygienic Congress recently held at Vienna, delivered a very interesting address on Enteric Fever. In referring to the etiology of the disease, he stated that whatever be the primary origin or nature of this affection, it is now certain that it may be propagated through the following principal agents: drinking water, the air which we breathe, the soiled linen of typhoid patients, and through the hands of the nurses attending them. These means of propagation, he added, have long been recognised, but they were hypothetical, whereas now it is possible to assign to each of these agents its proper position in the genesis of the disease, drinking water being the principal vehicle of the germs of typhoid fever, for in ninety-nine cases out of a hundred the cause has been clearly traced to it. Thus it may be seen that, whether the disease owes its origin to the decomposition of organic matter or to a specific virus, it will be easy, by

Digitized by Google

appropriate means, to render epidemics of enteric fever, if not impossible, at least extremely rare.

In connexion with this subject, I may mention that during the epidemic of typhoid fever which recently prevailed at Belvès, four bottles filled with water drawn from fountains of the town were forwarded to the Academy of Medicine. This water was subjected to chemical analysis by two eminent chemists attached to the Academy, who found an exaggerated proportion of the chlorides and of organic matter. Dr. Chantemesse made a bacteriological examination, and found the bacillus of typhoid fever in the water of one of the fountains.

FURFUROL IN ALCOHOL.

At the meeting of the Academy of Medicine of last week M. Bacchi read a note on the importance of the purification of alcohol for drinking purposes. According to the author, all alcohols employed for the manufacture of spirituous liquors contain furfurol in variable quantities, and consequently are more or less injurious. To remove this furfurol it is necessary to distil the alcohols according to Bang's procedure, which he considers the only effectual one, in which case the alcohol only produces the phenomena of ebriety without any convulsifying symptoms. M. Bacchi, however, omitted to inform the Academy as to the nature of Bang's method. A description of furfurol was then given. It is met with particularly in the alcohols of grain, such as oats, rye, and barley. It is obtained by the action of sulphuric acid on oatmeal or on bran, or, better still, by the action of sulphuric acid on a mixture of sugar and starch, with binoxide of manganese. It is a colourless liquid, becoming rapidly brown under the influence of the air, and it possesses an odour recalling at the same time that of the oil of cinnamon and that of bitter almonds. When it is administered to animals in a dose of a few cubic centimetres, its toxicity immediately becomes evident; one observes almost instantaneously tetanic symptoms and genuine attacks of epilepsy, whilst the respiratory movements become slackened and are soon completely arrested. These experiments throw a great light on the pathogeny of alcoholism, and furnish the explanation of certain contradictory facts tending to admit a semeiology differing according to the country in which alcoholism is observed. In Ireland and in Scotland, for example, one frequently observes in acute alcoholism attacks of epilepsy; whereas in France these accidents are noticed only in drinkers of "absinthe," "bitters" (a liqueur), and "vermouth." This is owing to the fact that in these countries the workpeople and peasants drink not only alcohols of grain, but also the residue left by these alcohols after distillation. What is now known of alcohols of industry explains the toxic action of the greater part of brandies and of rum delivered for the consumption of the public. All these spirituous liquors are alcohols by a sort of irony termed *supérieurs*, more or less adroitly aromatised. Drs. Laborde and Magnan have made combined researches on the toxicity of alcohols termed *supérieurs* and of *bouquets artificiels*, the results of which have been recently communicated to the Society of Public Medicine and Hygiene, and may be summarised as follows: In 1869 the proportion of alcoholic patients admitted into the asylums of the Department of the Seine attained, of the total of all admissions, including children and epileptics, the proportion, already very high, of 26 per 100 for men and 5 per 100 for women. At the end of the siege of Paris and of the Commune the admissions into the Sainte-Anne Asylum rose to 48 per 100 of alcoholics; then there was a fall from 1872 to 1875; the annual average oscillated between 17 and 19 per 100, to rise again at the end of the latter year. In 1886 the average rose to 25 per 100, and the first half of the year 1887 gave an equally large proportion. With reference to liqueurs and bouquets, these investigators remark that liqueurs were formerly the product of the distillation of the alcohols of wine, holding in dissolution aromatic substances, whereas now manufacturers simply add essences and sugar to alcohol, more or less rectified. The liqueur termed "absinthe," which frequently contains salicylate of methyl, produces, besides ebriety, with loss of sensation and of motion, veritable attacks of epilepsy. I cannot here give an account of all the liqueurs referred to in the communication of Drs. Laborde and Magnan, but will conclude with their just remark, that the distillateurs are largely responsible for the physical, intellectual, and moral degeneration of the populations resulting from the products employed by them.

Paris, Oct. 4th.

THE SERVICES.

Deputy Surgeon-General Bradshaw, at present in medical charge of the Northern District at York embarked in the *Euphrates* troopship on Wednesday last for service in India.

Deputy Inspector-General John Caldwell, R.N., died on the 29th ult., at Hartfield-road, Wimbledon, in the fifty-ninth year of his age.

WAR OFFICE.—Army Medical Staff: The surname of the Surgeon-Major whose promotion to the rank of Brigade Surgeon was notified in our issue of the 24th ult., is MacAdam, and not as therein stated.

INDIA OFFICE.—The Queen has approved of the retirement from the Service of the undermentioned officers of the Indian Military Forces:—Brigade Surgeon David William Trimnell, Madras Medical Establishment (dated Aug. 1st, 1887); Surgeon-Major William Nolan, M.D., Bombay Medical Establishment (dated Sept. 24th, 1887); Surgeon-Major Francis Jones, Bombay Medical Establishment (dated Sept. 1st, 1887). The undermentioned officers have been granted a step of honorary rank on retirement:—Brigade Surgeon James Champion Penny, M.D., Bengal Medical Establishment (dated June 3rd, 1887), and Brigade Surgeon David William Trimnell, Madras Medical Establishment (dated Aug. 1st, 1887), to be Deputy Surgeons-General.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Charles Morton has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated September 27th, 1887). Fleet Surgeon James Nicholas Joseph O'Malley has this day been placed on the retired list, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets. The following surgeons have been promoted to the rank of Staff Surgeon in Her Majesty's Fleet:—Charles Albert Macaulay, M.D., and Christopher Pearson, M.A., M.D. (dated September 30th, 1887).

The following appointments have been made:—Staff-Surgeon C. A. Macaulay to the *Constance*, and Staff-Surgeon Christopher Pearson to the *Gannet*, reappointed on promotion (dated Sept. 30th).

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Northumberland Fusiliers: Surgeon T. Stainthorpe resigns his commission; also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the battalion on his retirement (dated Oct. 5th, 1887).

Obituary.

FRANCIS OGSTON, M.D.

BY the death of Dr. Francis Ogston, at the advanced age of eighty-four, which occurred at his residence at Aberdeen on the 25th ult., one of the few remaining links that bind the present with the early part of the century is removed, and the connexion with the foundation of the Medical School at Aberdeen, so far as living representatives is concerned, is entirely snapped. Born in Aberdeen, Dr. Ogston received his early education in that city, and subsequently studied medicine at Edinburgh, where, in 1824, he took the degree of M.D., and became a Licentiate of the Royal College of Surgeons. In 1832 he was appointed Lecturer on Medical Jurisprudence in Marischal College and University, Aberdeen, and in 1857, when that lectureship was converted by the Crown into a professorship of Medical Logic and Medical Jurisprudence, he was elected to the post. On the union of King's and Marischal Colleges in 1860 he was transferred to the same chair in the University of Aberdeen, the duties of which he continued to discharge down to the time of his retirement in 1883. He was therefore a teacher in the University for half a century, and was for a quarter of a century professor both of Medical Logic and Medical Jurisprudence. Dr. Ogston acted for a long period as police surgeon; for several years he held the office of Dean of Faculty; and for two separate terms he represented the Senatus in the University Court. Subsequently to his retirement, the University to which he had been so deeply attached, and which he had served so well, conferred upon

Digitized by Google

him (in 1885) the honorary degree of LL.D. Dr. Ogston contributed several papers on medico-legal and pathological subjects to various British and foreign journals.

DR. JOSEPH MEYER.

ON the 25th ult., at Berlin, the Geheim-Medicinal-Rath, Professor Joseph Meyer, died at the age of sixty-six. He died, indeed, at his post as director of the Royal University Polyclinic. No Berlin physician enjoyed a higher reputation than he among his professional brethren and the general public. He first became favourably known as assistant physician to the late Professor Schönlein, at whose death he was called to fill the onerous position of directing physician of the Charité-Krankenhaus. On the death of Professor Romberg he succeeded that able pathologist in the superintendence of the University Polyclinic, and discharged its duties with exemplary skill and success till his decease. Some years before he had been nominated Professor Extraordinary in the University, and in the course of last session he was promoted as Geheim-Medicinal-Rath, a high professional honour. The lay journals of Berlin associate themselves with the medical in deploring the loss of an eminent citizen as well as of a valuable professional adviser.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates to practise as Licentiates of the Society on Sept. 19th:—

Yunge-Bateman, Marcus George, Folkestone.
Beaumont, William Henry, Whaddon, Royston.
Bulst, James Joseph, Pembroke-terrace, Cardiff.
Clarke, Edward Albert, Manchester-road, Denton.
Hemming, John Joseph, Fitzroy-road.
Ledward, Milton Prentice, York-street, Cheetham, Manchester.
Millington, John Perrett, High-street, Wolverhampton.
Spreat, Frank Arthur, Weymouth-street.
Stevens, William Henry Arthur, Droitwich.

The following gentlemen passed the examinations in Surgery held on Sept. 14th, 15th, 28th, and 29th:—

Bell, Walter Whilmarsh, Westminster Hospital.
Blacklock, John, Owens College, Manchester.
Dickson, Herbert Edward Balmain, Edinburgh.
Marsh, Alfred Herbert, Owens College, Manchester.
Mc Oscar, John, Middlesex Hospital.

THE Aberdeen Infirmary Jubilee Extension Fund amounts now to £25,140.

PRECAUTIONS AGAINST TRICHINOSIS.—Small quantities of pigs' meat coming from Poland into Silesia are now examined at any of the toll stations at a fee of 6*d*.

THE measles epidemic in the Hebrides is still spreading, and during the past few days has assumed rather serious dimensions.

IT is reported that in the course of the interesting excavations at Pompeii, a wooden case has been dug up containing a complete set of surgical instruments, many of which are similar to those used in the present day.

THE FELDSHER SCHOOL AT KAZAN.—The school for feldshers (a lower grade of practitioners) in Kazan is about to undergo some modifications, a department for training female feldshers being added.

GUY'S HOSPITAL MEDICAL SCHOOL.—The entrance scholarship in Arts, of 125 guineas, has been awarded to Mr. Richard L. Wason; and the entrance scholarship in Science, of 125 guineas, to Mr. Alfred Theodore Rake.

AT a meeting of the Sanitary Committee of the Newcastle Corporation on the 28th ult., it was decided to adhere to the arrangement which had been made not to admit patients suffering from small-pox into the new Fever Hospital.

AN outbreak of scarlet fever at the Liverpool School for Deaf and Dumb has necessitated its being closed, the inmates who have not been attacked being sent to their homes. The children affected have gone to the Liverpool Workhouse Hospital.

VOLUNTEER MEDICAL ASSOCIATION.—At a meeting held on Friday, Sept. 30th, the following gentlemen were appointed Surgeon Instructors to the Ambulance Department:—Surgeon J. Edward Squire, M.D., Volunteer Medical Staff Corps; Acting Surgeon W. Pearce, M.D., 20th Middlesex (Artists), R.V.

THE GREAT NORTHERN CENTRAL HOSPITAL.—It is reported that the committee of the Islington Jubilee Fund have paid over to this institution a first instalment of £2000 to enable the Building Committee of the hospital to meet liabilities now falling due without borrowing.

THE NEW HOSPITAL AT HASTINGS.—It is proposed, we understand, to formally open the new buildings on the 13th instant. This hospital is, we believe, the largest hitherto built in England with circular wards, and the opening ceremony will therefore be attended with special interest.

A PROSPECTUS of the various classes to be held during the ensuing six months in connexion with the Young Men's Christian Association at Exeter Hall has been issued. The subjects treated are numerous, and the advantages offered by the Association to young men who possess no friends in the metropolis are beyond doubt most valuable.

MEDICAL ADMINISTRATION IN TONQUIN.—*La Semaine Médicale* has received information that the medical service in Tonquin is wofully defective. In some of the provinces there are no doctors, and combatant officers and even sergeants have to act as surgeons. Again, it is stated that at certain of the stations some important drugs—as opium, quinine, and bismuth—are entirely wanting.

A GENEROUS OFFER.—An offer has been made to the Board of the Manchester Royal Infirmary of a cottage hospital for twenty beds in Hulme. The building will be erected and conveyed to the Board free from all debt, and suitably and completely furnished, provided that body wil undertake the management and the cost of maintenance of the patients when it is completely finished. The matter has been referred to the Infirmary Committee.

UTILISATION OF MILITARY HOSPITALS FOR CLINICAL INSTRUCTION.—Most of the Russian universities suffer from an insufficiency of clinical material in the hospitals connected with their medical faculties. An arrangement has now been made to admit students to the practice of certain military hospitals, the military medical authorities and the university faculties appointing assistants and lecturers in concert with one another.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The annual distribution of prizes to the students attending the school of this Society last session took place on the 5th inst., the ceremony of distribution being performed by the President, Mr. Michael Carteighe. The inaugural address was delivered by Sir Dyce Duckworth, and the Hanbury Gold Medal for Original Research in Natural History and the Chemistry of Drugs was gained by Brigade Surgeon W. Dymock of Bombay.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual meeting of this Society (the first meeting after the amalgamation) will be held at the Holborn Restaurant on the 21st inst., at 4 P.M. Amongst the business to be brought forward will be the presentation of the reports of two committees, that, namely, appointed to consider the amalgamation of the several Societies of Medical Officers of Health, and that deputed with the task of considering the proposal to establish a laboratory for the study of bacteriology, and other experimental methods of research. At the conclusion of the annual meeting the sessional meeting will be held, at which the president-elect will deliver an address.

Digitized by Google

THE HOSPITALS ASSOCIATION.—The first meeting of the fifth session of this Association will be held at the Library of the Society of Arts, John-street, Adelphi, on the 12th inst., at 8 P.M., under the presidency of Sir Andrew Clark (president), when a paper will be read by Mr. Henry C. Burdett explanatory of the scheme for the formation of a "National Pension Fund for Hospital Officials and Trained Nurses." Invitation cards may be obtained of Mr. Howard J. Collins, Secretary, Norfolk House, Norfolk-street.

THE FRENCH VETERINARY ASSOCIATION.—The Association of French Veterinary Surgeons, which has just met at Bordeaux, expressed an opinion that the inspection of meat ought to be very much more real than it has been. A vote was also unanimously passed expressing the view of the Association that veterinarians ought to be admitted as members of the National and Departmental Sanitary Councils. A vote passed last year at the meeting held at Lille, to the effect that one of the diplomas of Bachelor of Letters or Bachelor of Sciences ought to be compulsory for veterinary students, was confirmed.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADIE, ALFRED A., L.R.C.S., L.R.C.P.Ed., has been appointed House-Physician to the Royal Infirmary, Glasgow.

ATKIN, CHAS., F.R.C.S, L.R.C.P.Lond., has been appointed Honorary Assistant Surgeon to the Sheffield General Infirmary.

BROGDEN, RICHARD W., M.B., B S. Lond., has been appointed Physician to the East Suffolk and Ipswich Hospital.

BULLMORE, W. KING, M.D.St.And., M.R.C.S., has been reappointed Medical Officer to the Falmouth Dispensary.

COCKING, W. TUSTING, M.B.Lond., M.R.C.S., has been appointed Honorary Assistant Physician to the Sheffield General Infirmary.

DUNCAN, ALEX., M.B., C.M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

EDGAR, JOHN, B.Sc., M.B., C.M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

GRAHME, WILLIAM D., M.B., C.M., has been appointed House-Physician to the Royal Infirmary, Glasgow.

GRANT, DAVID, M.A., M.D. Edin., Lecturer on Materia Medica at the University of Melbourne, has been appointed Physician to Out-Patients at the Melbourne Hospital; and Examiner in Therapeutics, Dietetics, and Hygiene at the University of Melbourne.

HALLAM, ARTHUR, M.R.C.S., L.S.A., has been appointed Honorary Assistant Surgeon to the Sheffield General Infirmary.

HILL, C. M., M.R.C.S., L.R.C.P.Lond., has been appointed Assistant House-Surgeon to the Halifax Infirmary and Dispensary, vice H. Fitton, resigned.

JAMES, ALFRED, M.R.C.S., L.S.A., has been appointed Medical Officer for the Workhouse of the Biggleswade Union.

MCEWEN, HENRY C., B.Sc., M.B., C.M., has been reappointed House-Physician to the Royal Infirmary, Glasgow.

MCLENN, ALEX. D., L.R.C.S., L.R.C.P.Ed., has been appointed House-Physician to the Royal Infirmary, Glasgow.

MILNER, H. TAYLOR, M.A., M.B.Oxon., M.R.C.S., has been appointed Resident Surgical Officer to the Convalescent Hospital at Cheadle in connexion with the Manchester Royal Infirmary.

ORD, FRED. W., L.K.Q.C.P.I., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

PLEWS, PAUL RHODES, L.R.C.P.Ed., L.F.P.S.Glas., has been appointed Medical Officer for the Fourth District of the Bethnal-green Union, vice Defriez, deceased.

PORTER, W. SMITH, M.D.Dur., M.R.C.S., has been appointed Honorary Assistant Physician to the Sheffield General Infirmary.

ROBINSON, HARRY W., M.B., C.M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

SHIPLEY, A. E., B.A., has been appointed Demonstrator of Comparative Anatomy in the University of Cambridge.

THOMSON, GEORGE, M.B., C.M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

THORBURN, WILLIAM, M.D., B.S., B. Sc. Lond., F.R.C.S., has been reappointed Surgical Registrar to the Manchester Royal Infirmary.

WATKINS, HAROLD F., M.B., C.M.Ed., has been appointed Medical Officer for the Fifth District of the Mansfield Union.

WETWAN, WILLIAM A., M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Bridlington Urban Sanitary District.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM BOROUGH ASYLUM.—Clinical Assistant. Board and residence, but no salary.

CUMBERLAND INFIRMARY, Carlisle.—Assistant House-Surgeon. Salary £40 per annum, with board and lodging.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Registrar and Chloroformist. Salary £30 per annum, with an additional £20 if the post is held for twelve months.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. — Junior Resident Medical Officer. Salary £50 per annum, with board and residence in the hospital.

INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTON DISPENSARY.—Senior House-Surgeon. Salary £60, rising to £70, with board and residence.—Also Junior House-Surgeon. Salary £50, rising to £60.

NATIONAL SANATORIUM FOR CONSUMPTION AND DISEASES OF THE CHEST, Bournemouth.—Resident Medical Officer and Local Secretary. Salary £150 per annum, with board and lodging.

NORTH-WEST LONDON HOSPITAL, Kentish-town-road.—Assistant Resident Medical Officer. Board and residence in the hospital.

NOTTINGHAM GENERAL HOSPITAL.—Resident Medical Assistant. Board, lodging, and washing, but no salary.

ROYAL BERKS HOSPITAL, Reading.—Physician.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Pathological Curator.

ROTHERHAM HOSPITAL.—Assistant to the House-Surgeon. Rooms, commons, and washing, in lieu of salary.

ROYAL LONDON OPHTHALMIC HOSPITAL, Blomfield-street, Moorfields, E.C.—Junior House-Surgeon. Salary £50 per annum, with board and residence.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Physician.

TAUNTON AND SOMERSET HOSPITAL.—Honorary Surgeon.

Births, Marriages, and Deaths.

BIRTHS.

COX.—On the 3rd ult., at Cape Town, South Africa, the wife of J. Herbert Cox, M.R.C.S.Eng., L.R.C.P.Lond., of a son.

MURRAY.—On the 1st inst., at The Parks, Tenbury, Worcestershire, the wife of W. Berkeley Murray, M.D., of a son.

ROSSITER.—On the 3rd inst., at Cairo Lodge, Weston-super-Mare, the wife of George Frederick Rossiter, M.B.Lond, of a son.

WYATT.—On the 30th ult., at Stamford-hill, the wife of W. T. Wyatt, M.A., M.D., of a son.

YOUNG.—On the 26th ult., at Rose Bank, Merton-road, Bootle, near Liverpool, the wife of T. Frederic Young, M.K.Q.C.P., M.R.C.S., of a son.

MARRIAGES.

CARTER—GRANT.—On the 23th ult., at Christ Church, Bootle, Liverpool, by the Rev. A. T. Scott, M.A., Vicar of Tunbridge Wells, assisted by the Rev. F. C. Master, Vicar of the Parish, Godfrey Carter, L.R.C.P., M.R.C.S., youngest son of J. H. Carter, formerly of Leeds, and grandson of the late J. Carter, Banker, of Barnsley, to Harriette Louise, eldest daughter of Duncan E. K. Grant, retired Commander, Royal Navy. (No cards.)

LOWNDS—REED.—On the 5th inst., at Christ Church, Sunderland, by the Rev. C. Wadsworth, M.A., James Richard Lownds, Camb., L.R.C.P., L.R.C.S.Ed., eldest son of James R. Lownds, M.R.C.S., L.S.A., of Newcastle-on-Tyne, to Patty, only daughter of Chas. H. Reed, J.P., Sunderland.

STACEY—HOWARD.—On the 5th inst., at St. Anne's Church, Stamford-hill, by the Rev. J. D. Letts, Vicar, assisted by the Rev. R. L. Allwork, Henry George Stacey, F.L.S., &c., eldest son of Samuel Lloyd Stacey, Esq., of 300, High Holborn, to Mary Josephine Howard, eldest daughter of Joseph Howard, Esq., M.P., of Tottenham, and granddaughter of the late John Eliot Howard, Esq., F.R.S.

WEBB—HAMMOND.—On the 1st inst., at Rotherham Parish Church, William Edward Webb, Surgeon-Major, Army Medical Staff, to Ellen Louisa, eldest daughter of Major Lawrence Hammond, late 90th Light Infantry.

DEATHS.

BUCK.—On the 4th inst., William Rigar Buck, M.A., M.D.Cantab., formerly Honorary Physician to the Leicester Infirmary, aged 39.

CALDWELL.—On the 29th ult., at Hartfield-road, Wimbledon, John Caldwell, Deputy Inspector-General, R.N., in his 59th year.

CHETTI.—On August 31st, at Madras, India (of heart disease), P. Parthasarathi Chetti, M.B., C.M., B.Sc.Edin., aged 27.

MOORE.—On the 23rd ult., at Liverpool, John Percy Moore, M.R.C.S., aged 76.

SIM.—On the 29th ult., at Aberdeen, John Sim, M.R.C.S., aged 84.

WALFORD.—On the 2nd inst., at Argyll-street, W., Robt. Walford, M.B., aged 36.

WHEELER.—On the 2nd inst., at Reigate, Wm. Hy. Wheeler, M.R.C.S., L.R.C.P., aged 34.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

AT LAST!

IT is gratifying to learn that humanity, to say nothing of good taste, has asserted itself at last among a section at least of the fairer portion of the fashionable world. At a conference of ladies held in Bond-street on the subject of dress, it was decided a few days ago that the plumage of small birds should no longer be considered as fashionable trimming for robes or bonnets. Let this decision become accepted by the community in general, and a foul blot on our civilisation will have been removed.

A Medical Muser.—Professor Gamgee, in his work on Yellow Fever (1879), quotes the late Mr. R. Clarke, surgeon to the natives on the West Coast of Africa, who, in a valuable paper in the 1863 volume of the Transactions of the Epidemiological Society, wrote to the effect that yellow fever "is wholly unknown" on that coast. Its prevalence in Africa seems never to have been brought about except by importation through infected shipping. The paludal fever of the West Coast of Africa is different from yellow fever. Yellow fever remains the only disease which in England admits of quarantine, and it is so dealt with purely for commercial purposes. The action taken at the Motherbank station would depend on the statement of the cause of death; and we doubt whether, if yellow fever were recorded as such cause, the authorities would have power to act otherwise than by detaining the vessel.

Mr. Fitzpatrick (Moville).—No, the only methods in use are the removal of the fluid by means of the aspirator or trochar and cannula, and possibly, for purposes of diagnosis, the hypodermic syringe.

J. N. (Cape Town).—The gentleman named has retired from the service.

THE DIETARY OF THE POOR.

To the Editors of THE LANCET.

SIRS,—At the recent meeting of the British Medical Association in Dublin Dr. Lindsay of Belfast read a paper on the dietary of the poor. This subject is a truly vital one, and has had too little attention paid to it—the nation being what its food makes it. Medical men individually can do but little, as advice on the subject is scarcely ever acted upon continuously and systematically. Dr. Lindsay says that the diet of the poor is meagre and insufficient. But this is by reason of its lacking in quality rather than quantity; and to remedy this evil effectually, I can see no way except to make the relative value of our various articles of diet a compulsory subject in all schools, and the elements of physiology also, if not already taught. It is only by beginning at the beginning that we can hope eventually to effect a change for the better in the stamina of our nation.—I am, Sirs, yours faithfully,

Aghot, Sept. 27th, 1887. J. WINTHROP WOODRUFF.

MEDICAL EDUCATION IN NEW ZEALAND.

MR. FRANCIS B. HUTCHINSON, M.R.C.S., &c., in a presidential address delivered recently to the members of the Wellington Philosophical Society, speaking of the present condition of medical education and practice in the colony of New Zealand, remarked as follows:—"It is not possible, with the available anatomical, pathological, and clinical material, that an efficient practical training can be given. Here 'cram' must reign. Hence I believe that the rule lately passed by the Senate, allowing men to graduate in medicine who have had no other opportunities of study than those afforded within the colony, is a mischievous one. The probable result, if carried to any extent into effect, will be that our University will take rank, as regards medicine, with those of the Western States of the Union, known as 'one-horse.' I trust the obnoxious rule will be rescinded, and in this case I speak with the more confidence as I do not express only my own opinion, but that of the members of the Medical Congress lately held in this city."

Ashton Street.—Under the fifth section of the 6 & 7 William IV., c. 89, a coroner is not only enabled, but required, to refuse fees for medical evidence given at his court in the matter of "persons dying in any public hospital or infirmary, or in any building or place belonging thereto or used for the reception of the patients thereof, or dying in any county or lunatic asylum, or in any public infirmary or other public institution, whether supported by endowments or by public subscription"—that is to say, that in such cases the medical officer whose duty it may have been to attend the deceased person as a medical officer of such an institution shall not be entitled to fees or remuneration. The late Bill is merely a consolidating one; it was passed with a view to further enactment of alteration and reform in a subsequent session. It leaves untouched the question referred to in the letter of our correspondent.

SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—With reference to Mr. Donnellan's explanation as to the primary cause of sea-sickness, might I ask why the "contents of the stomach being shaken about" should make the "food act as a foreign body"? Are not the contents of the stomachs of those persons who lead active lives daily "shaken about" in either their avocations or amusements? We do not hear of hard riders across country being specially liable to sickness of the stomach, nor is emesis, as far as I know, common in the hunting field, though I should say that the stomach recognises little difference in the motion conveyed to its contents in these cases from that which it experiences on board a large steamer in a heavy sea. Then if the nausea was due to the food acting as a foreign body, why should it not cease when the foreign body is effectually removed by vomiting, as its stay in the stomach can hardly have been long enough to have set up an irritation which would outlive its removal? It cannot have escaped Mr. Donnellan's notice that the remedy which he instances to prove his theory of "gastric irritation" (a mustard leaf or other counter-irritant) is often of similar value where the vomiting is due to cerebral causes. I do not venture to explain the cause of sea-sickness, but I do think from a fair experience of this complaint that its causes are more cerebral than gastric, and I certainly believe that the theory as to the disturbance of the circulation in the semicircular canals is as tenable as any yet advanced. I am, Sirs, yours faithfully,

Stratford-on-Avon, Oct. 3rd, 1887. S. A. L. SWAN, M.D.

To the Editors of THE LANCET.

SIRS,—I was somewhat surprised to see Mr. Donnellan, in THE LANCET of Oct. 1st, upholding the antiquated theory of "shaking about of the contents of the stomach" as a cause of sea-sickness. He does not, however, make any attempt to explain how the motion of the vessel is communicated to these contents. Even if he had succeeded in this, that would not throw any light on the fact that sea-sickness is most common when the stomach is empty, and not at all uncommon in nervous people when sailing upon a smooth lake or river. We have definite proof of nervous apprehension being the initial factor. Now this will not produce "shaking about of the contents of the stomach," though I see no reason, arguing from analogy, why it should not cause an inefficiency of the pyloric sphincter. At any rate, if there be any mechanical derangement, this is as likely as anything else. With regard to the brain, probably there is first anæmia, then congestive hyperæmia produced by the vomiting, and in long voyages this is likely to be a more or less permanent cause for the incessant sickness.

I remain, Sirs, yours very truly,

October 4th, 1887. J. RUSSELL HARRIS, M.D.

THE PRESYSTOLIC MURMUR.

WE have received several letters on the subject raised by Dr. Dickinson in a paper now appearing in our columns. We reserve the publication of the communications until next week, when Dr. Dickinson's paper will have been completed.

M.S.—As the case is represented by our correspondent, we think he would not be justified in giving a certificate.

Digitized by Google

HOLIDAY AMENITIES.

Enquirens.—Our correspondent has three courses before him—either to appropriate the case, or to share the fee, or to hand over both the patient and the fee to the ordinary medical adviser. The last course is the kindest; but there would be nothing unreasonable in the second. We do not like the first. The fact that a man on his holiday has a partner who is not acceptable to his patients does not entitle him the less to the consideration of his professional neighbours.

De Lunatico Inquirendo.—1. Our correspondent may receive one idiot only into his house without a licence. The patient must be under order and two medical certificates, copies of which must be sent to the Commissioners in Lunacy.—2. There is no book to guide a practitioner intending to start an idiot asylum. A licence for such an institution would probably only be granted to an applicant who had had some experience in the treatment of insanity and diseases of children; and not then unless it could be shown that there was need for such an institution in any particular district. The new Bill awaiting enactment proposes to make legal the admission of an idiot to an asylum under one certificate.

Dum Spiro Spero is referred to an article in the Students' Number of THE LANCET, published on Sept. 3rd last.

THE "DOECKER" PORTABLE HOSPITAL.

To the Editors of THE LANCET.

SIRS,—As sole agents for Doecker's Patent Portable Houses, and after communicating with the manufacturers, we take the liberty to call your attention to the unfairness you have allowed to creep into an article entitled, "Ducker Portable Hospital," in your issue of the 17th ult. We are sure that you cannot have been aware how misleading the article in question is to the public, and we feel equally confident that you will do us justice by publishing the following remarks.

It was Doecker's (not Ducker) Patent Portable Houses that obtained the prize at the international competition for ambulance barracks which took place at Antwerp in September, 1885, under the auspices of the Red Cross Society of Geneva, the prize consisting of a gold medal and £200 offered by the Empress of Germany, a gold medal having previously been awarded to the Doecker Hospital Huts at the Hygienic Exhibition in Berlin, 1883, and presented by H.I.M. the Empress Augusta to Captain de Doecker. We do not wish to enumerate the awards the Doecker Patent Portable Houses have obtained; suffice it to say that they have taken the highest prizes wherever they have been in competition, and that the imitations which have sprung up are sufficient proof in themselves of the superiority of the original Doecker Hospital Huts. The Ducker Portable Hospital, described in the article referred to, is a close imitation of the original Doecker Patent Portable Houses; but the amount of air-space has been curtailed. Taking the latter into consideration, an original Doecker Portable Hospital for the same number of beds will be about 5 per cent. cheaper than its imitation. The agents of the company making the Ducker Hospitals have tried all means to drive Doecker's Patent Portable Houses out of Berlin and Paris without result, and they are evidently anxious to make a similar attempt here. We enclose full particulars of Doecker's Patent Portable Houses, also copy of a letter from a hospital authority to Mr. Trier, the latter formerly the representative of the manufacturers in London, and apologising for thus far trespassing upon your valuable space,

We are, Sirs, yours very truly
(*pro* Banner Sanitation Co.),
A. B. HUBERT, Manager.

Northumberland-avenue, W.C., Oct. 1st, 1887.

HOSPITAL APPOINTMENTS IN BUENOS AYRES.

To the Editors of THE LANCET.

SIRS,—The post of house-surgeon to the British Hospital at Buenos Ayres was advertised in THE LANCET a few weeks ago as being vacant. Applications were to be sent to a firm in London (acting as agents) on or before September 30th. I sent in my application on September 23rd, and it was returned, the agents saying that they had received directions (not from the committee of the hospital) to do so, as so many applications had been sent in. I had taken a good deal of trouble about the appointment, and as I have some very influential friends in Buenos Ayres I thought I stood a good chance of getting it. I think that the application should have been submitted to the committee of the hospital. I should be obliged if you would publish this.

I am, Sirs, yours faithfully,
Sept. 30th, 1887. M. C. M.

*** We have received another letter to the same effect.—ED. L.

A QUERY.

To the Editors of THE LANCET.

SIRS,—I have a patient, an interesting lad of eight, the son of a collier, who two years ago had a very severe attack of scarlatina, and, as the result, lost both eyes and became completely deaf. He has now forgotten most of the words he knew; but in all other respects he is a strong, healthy boy. I shall be exceedingly thankful to any reader of THE LANCET who could inform me whether there exists in this country any institution where this boy, who is absolutely deaf and blind, could be received and taught.

I am, Sirs, your obedient servant,
Oct. 5th, 1887. B.

HOLIDAY COLONIES.

THE movement for sending poor children from large towns into the country or to the seaside during the holidays in "colonies" is making considerable progress in France. The society established by M. Gréard has provided for 600 Paris children, and this year a small "colony" has been taken from Bayonne to Saint Jean de Luz for three weeks with excellent results. According to M. Delvaille of Bayonne, the average increase in weight was 1·039 kilog., in height 6 millim., and in chest measurement 12 millim. Under ordinary circumstances the increase in weight would have been only 250 grms. M. Delvaille points out that it is during the holidays that the children are most subject to all the evil and unhygienic influences of their homes, which are he thinks much more serious hindrances to their health than even intellectual overwork.

In doubt.—1. No; the consolidated pay is supposed to cover hotel and travelling expenses. Of course, a medical officer travelling in India on duty obtains a railway warrant from Government.—2. Medical officers of the Indian Medical Service are supposed to do duty with the native troops when on military service. A considerable proportion of medical officers are engaged after a time on civil duties.

THE NAVAL MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—If a naval executive officer wishes to refresh his memory and keep himself in touch with the various improvements, alterations, &c. in the subjects of gunnery or torpedo practice and theory, he may, with the approval of the Admiralty, pass through a short course on board one of the ships established for the purpose. Now, a naval medical officer has no such facilities afforded to him in his special branch; and, as a rule, however anxious he may be to keep up with the times, he is absolutely unable to do so. A surgeon may be appointed to a naval hospital for fifteen or eighteen months after serving two commissions of three years and a half to four years each in some out-of-the-way parts of the world, during which time his practice has been of the scantiest description, usually one type of disease prevailing. He is then called upon to treat a hundred or two hundred cases of general medical and surgical diseases or injuries, after almost a blank, as far as his profession is concerned, of seven or eight years. Of course, he may endeavour to keep up his knowledge by reading the medical journals and new works; but reading without the chance of applying the principles taught is at best a thankless task. What I would suggest is that a surgeon should be allowed, if he desire it, to attend a London hospital or other recognised medical school for a short period, say, three or six months, at any time after he has served six years. The time so spent to count as full-pay time, on the condition that as soon as convenient after its expiration the medical officer should pass an examination which should prove that the time so spent had been to the benefit of the service. If he fail to pass, the time should be counted as half-pay. I feel confident that this suggestion (perhaps modified in several ways), if acted upon, would prove a great boon to those medical officers of the navy who do not wish to degenerate into mere machines of routine, and who really desire to do their duty efficiently to the service and their country.

I am, Sirs, yours truly,
Oct. 2nd, 1887. SURGEON, R.N.

HERPES AND VACCINATION.

To the Editors of THE LANCET.

SIRS,—If the following case be deemed of sufficient interest, I should be glad if you would insert it in THE LANCET.

C. F——, aged nine years, came to me early in September suffering from herpes costalis, which I treated with hot bathing and zinc ointment, and which was quite cured by Sept. 9th. On the 13th I revaccinated him, and on examining the arm on the 20th inst. I found there was a distinct and typical crop of herpes surrounding the arm for about three inches above and the same distance below the vaccine vesicles. It would appear that the irritation of the vaccination had brought out this fresh crop; and though only in the immediate vicinity of the vesicles these latter were quite ordinary, seeming not to be in the least degree altered by the herpes.

I am, Sirs, yours faithfully,
Montague-place, E., Sept. 20th, 1887. CHAS. J. THOMPSON, M.R.C.S.

A NEW METHOD OF VENTILATION.

A CORRESPONDENT asks for the address of Messrs. Young and Moss, which we have unfortunately mislaid.

ERRATUM.—In line 15 of Dr. Peter Hood's letter, published last week, page 682, for "the oyster preparation of the London Pharmacopœia" read "*creta* preparata of the London Pharmacopœia."

Introductory Address

DELIVERED AT THE

OWENS COLLEGE, MANCHESTER,

At the Opening of the Medical Session 1887-88,

BY SIR JAMES PAGET, BART., F.R.S.

I WISH to speak on the utility of scientific work in the practice of medicine and surgery; not in the sense of using, for the purposes of practice, all the medical scientific knowledge that has been acquired, but in that of using, after a scientific manner, all the opportunities which practice affords for the acquirement of more knowledge. In our calling careful practice and scientific study should be inseparable; they always may be so; and I want to urge that everyone of you should be, to the full measure of his ability, a scientific student both now and all his life-long. I have seen enough to make me sure that they who, whether they know it or not, do their work after a scientific manner are the best practitioners, and contribute most to the general increase of knowledge. Although, therefore, as I have said, my chief object may be to urge the use of science for gaining fresh knowledge by the study of what may be observed in practice, yet I would have it always understood that whoever will thus work will be all the more useful to his patients, whatever kind of practice he may be engaged in.

I shall not attempt to define "science" or "scientific." Like many of the most useful words in our language, they do not admit of any exact brief definition. What I mean by them may appear as I go on. Many of you are beginning, others have lately passed through, what are especially called your scientific studies, or the scientific part of your curriculum. I could wish that they were not so called, for it seems to imply that the studies following them are not scientific; and to some minds it implies that the studies which are called scientific are not useful—both of which are serious errors. For, to any of you who so choose, clinical study, whether in your pupilage or in your practice, whether in hospitals or in private, may be made as scientific, in any fair meaning of the word, as either chemistry or physiology; and to those of you who so choose the studies of the first two years of the curriculum may be made very useful in after life.

Whether these first years' studies are the best possible, or too many or too few, I shall not now discuss. I have spent too many hours on this question in other places to be willing to spend minutes on it in this. You must take the scheme of education which senates and councils have devised for you and do your best, and you may be sure that, when you have done your best, you will be far more fit for what is next to come than you are now. For, in all these first years' subjects, things are to be learned which, though they may be erroneously called "the foundations" of those to be learned later, are yet of great importance for the understanding of what is to follow. You may learn in them methods of study and the use of instruments for observation which are of the highest utility; and if you will work earnestly at them, these studies will supply a very good training for that scientific method of study which ought to be associated with all the work of your after life. It is, I believe, by this early cultivation of a scientific mind, even more than by the facts which they may teach, that these earlier subjects of medical study may achieve their greatest good. The teaching and continued study of these subjects will be the work of a few, and a constantly decreasing proportion of these few will be engaged in practice; but this makes it the more necessary that the scientific mind and method, the love of knowledge and of the means of gaining it, may abide in all those who take to the life which is called practical, and which may be scientific and is best when it is so.

Now, the first, and certainly in student life the only, safe means for becoming scientific in our profession is the training of the mind in the power and habit of accurately observing facts. Medicine and surgery are eminently a science of observation; deductions from facts are always unsafe; I believe that they have done far more harm than good; and, for the most part, when sufficient facts have been collected and arranged, the general conclusions that may justly be drawn from them are nearly manifest. The main thing for progress and for self-improvement is accurate observation. Some seem to think it easy to observe accurately—they cannot doubt, as they say, the evidence of their senses. There are few greater fallacies. In scientific studies the evidence of the senses needs as much cross-examination as any evidence given in a criminal trial. Self cross-examination it may be, but it must be steady and severe. For by accurate observation we must mean not the mere exercise of the senses, not the mere seeing, or hearing, or touching of a thing, with some levity of thinking about it—we must not mean even the keenest use of the eye cultivated in microscopic work, or of the ear hearing sounds that to the uneducated sense would be inaudible, or the use of the finger with the most refined detective touch. All these higher powers of the senses you must acquire by careful study and practice, and you must learn to exercise them with all the attention with which a strong will can direct and watch them; but even all this, difficult as it is, is only a part of scientific observation. This must include, besides, an habitual constant watchfulness, the taking notice of all the conditions in which objects or events are found; their concurrence, their sequences, their seeming mutual relations, all their variations. To do this, and to do it again and again, and with constant care, whether it be in things occurring naturally or in experiments—to do this accurately and always is really very difficult. A few seem to have the power naturally; there are some born naturalists, some born physicists; you have had some here; but in nearly all men, and, you may safely believe, in yourselves, the power to observe accurately needs careful self-training, self-suspicion, and self-discipline.

If accurate observation were easy, how could we explain the oversights and the errors of which the evidences abound in the whole history of medicine, and which, I think, every one could find in a retrospect of his own work? Look at the history of discoveries. As a general rule, every discovery of things that can be observed tells of previous oversight or want of observation. Some discoveries, indeed, have followed quickly on the invention of improved means of observation, or on the advancement of knowledge clearing away some previous obscurities. These, it may fairly be said, could not have been made much sooner; but of far more it may certainly be said that the discoveries in each generation are evidences of the oversights, the defective or erroneous observations, of men of previous times—even of the best of them. Take some leading instances. All the facts which enabled Jenner to discover vaccination were within the range of his predecessors; they saw and heard of them, but they did not observe them; they all overlooked them, except the one farmer who vaccinated his children, but could not persuade others to follow his example. All the sounds on which Laennec established his system of auscultation were within the hearing of previous generations and of his elder contemporaries; many had heard them, but they did not listen as he did, and they did not observe the conditions in which the different sounds occurred—how each coincided with some diseased process or change of structure in the heart or lungs. All the facts by which Hunter was guided to his operation for aneurysm might have been obvious to other surgeons of his own and lately previous times. They did see them; they did not carefully observe them. I need not multiply examples. Look at any discovery of this or last year, and think whether it might not have been made in the previous year or some years ago; and when you find that it might have been and was not, though men of excellent ability were within reach of it, then you may feel that accurate and complete observation is a really difficult thing, and that for the fulfilment of your duty, whether to science or to your patients, you must cultivate the power of searching and observing with all your might.

I have been more than usually impressed with these thoughts after lately looking through many of my old case-books, and finding in them evidences of more oversights and errors of observation than I had imagined myself guilty of; and though I might console myself by the examples of the distinguished men who did not discover vaccination or the

Digitized by Google

use of auscultation and did not improve the treatment of aneurysm, yet it made me think that, as an act of penitence, I ought to try to make amends by warning some who are beginning such work as I have so failed in. For instance, among my records are those of nearly all the post-mortem examinations which I made nearly fifty years ago, when I was demonstrator of morbid anatomy at St. Bartholomew's Hospital. They are full and tedious; but the evidences of oversight and of errors in observation are many. I find, for example, complete and full records of the examinations of typhoid ulcers of the intestines; and they are regarded as illustrations of the typhus fever then supposed to be prevailing. Many others were thinking the same, many had thought so years and years before; but about the same time Sir William Jenner not only saw such ulcers, but accurately observed them, and he observed all the conditions with which they alone coincided, and he proved that they were characteristic of a fever essentially different from typhus. In the same records I find long descriptions of the morbid changes in different forms of venous and capillary embolism, but I wholly overlooked and missed their meaning till it was discovered by Virchow and my own pupil Kirkes, and by others more observant than myself. I saw all these things; they accurately observed them; they studied the associated facts; and embolism, which had been destroying healths and lives for ages in secret, was at last discovered.

Do not let me seem to suggest that I deserve credit for having seen these and other like things as if for discoveries for which others have been honoured. Far from this, these are evidences of that very oversight which I want to persuade you to avoid. It is a shame rather than honour to have seen a thing and not observed it; to have been within reach of a scientific truth and not have grasped it.

But, it may be said, these are examples of discoveries made in large fields of observation, and needing long and careful research among many cases; these are not within reach in ordinary practice. Look, then, at some simpler instances. Not a year passes but someone describes a disease of which we had no previous record—a spondylitis deformans, or some new form of myxœdema, an osteitis deformans, or some new manifestation of tubercle or cancer; it matters not what—a novelty. And the first case is thought unique, strange, and, by some, not much worth thinking of; but soon similar cases are found here and there, and the new disease seems hardly rare. I will not say that no new diseases ever appear. I have long maintained that they do: but they do not come among us on a sudden, and we may be certain, whenever a case of a new disease is observed, it is not the first that has occurred or the only one existing; similar cases have been overlooked, they have been within sight and have not been observed. And without doubt there are similar examples of oversight among us still. For example, a distinguished pathologist in Paris has lately described a disease which he names "acromegalie," with singular enlargement of the bones of the face and hands and feet. I cannot suppose that this disease is limited to France; it must, I think, be among us as well; but, so far as I know, no Englishman has yet observed it. Well, I blame no one unless it be myself; I want only to show by facts like these that it is very difficult to observe accurately, and that if you are to do your whole duty, either to your patients or to science, you must now and always study and practise the right methods of scientific observation.

I wish that the arguments for this were only in the oversights, the mere defects of observation. Unhappily the errors illustrated in all the history of medicine, and in much that is still in progress, are very numerous too. Facts, when not quite overlooked, are too often seen and recorded erroneously. I would not speak of such errors without a confession of having contributed to them, or without the fair motive of wishing to urge the best means for avoiding the like of them. For remember that many of them were made, or are being made, by men as honest as we are or ought to be, and as fairly in the pursuit of knowledge.

It would need some volumes to relate all the sources of error in scientific observation. I will mention only one, for I think it is the most frequent, and I should like you to be always watching against it. It is the habit that we have of inserting something of our own, something of our beliefs, of our expectations, nay even of our wishes, into that which we think or say that we observe. We expect facts or events to agree with what we believe that we know, and we make light of the differences and exaggerate the likenesses; we take no thought of what we call accidental exceptions; we think them unmeaning—as if anything in nature could be without meaning,—and we do not half observe them. In philosophy we can separate things from thoughts, the object from the subject; but in ourselves and in ordinary life they are mingled in every act of consciousness and reflection; and sometimes it is only by careful self-analysis and by habit studiously gained that we can separate them and observe simply and accurately.

There is a very common proverb that "seeing is believing," and many, as if trusting it, say, "I must believe what I see." It is often unwise to do so; for the sight, without the aid or control of other senses, is often fallacious. But there are many in every walk of life who, when they say "I believe what I see," might just as fairly say, "I see what I believe"; and these, though they are usually in the wrong, are usually the most positive in their assertions. They believe what they wish, and then they see what they believe; and then they become unable either to see or to believe anything contrary to their wishes—anything contrary to what they call their clear convictions. Well, as a man may see an unexpected likeness of himself in a caricature, so may we all see a defect of our own exaggerated in people such as these. We are all apt to see what we expect to see; to think that the knowledge already gained is so sure that that which is next to come must exactly agree with it. Our safeguard must be in careful scientific study, in the habit of observing without prejudice and with self-distrust, always remembering that everything brought within the range of human knowledge is brought within the much wider range of human error.

And here let me add that, however much the mechanism and other external helps for observation have of late been improved, our mental powers have not increased in the same degree; we are in ourselves as likely to observe erroneously as were our predecessors; in this sense we are not wiser than our fathers. It may even be doubted whether the improvements in the means of observing be more than in proportion to the much larger field and the more minute facts within reach of which we have been brought. It is comparatively easy now to see and do many things which used to be difficult or impossible; but it is not, therefore, easier to see and do new things. The higher we rise on the hill of knowledge the steeper and the more difficult does the ascent become. And we are not yet near the summit: it reaches up to Heaven.

I might speak of many means of helping ourselves in the cultivation of the power of accurately observing, such as reading—which is, perhaps, of all the most important,—and of drawing, collecting specimens, and many more; but I will speak of only one, which is far too often neglected. You will find it, I think, essential to scientific accuracy that you should have the habit of recording very carefully your observations and all the chief facts connected with them. No one should wholly trust his memory in such things; it may lose the facts, or, worse still, may gradually alter them; for, as belief and expectation and other mental states can affect the impressions which we derive from things even when they are present before us, so and much more can they affect those which we try to reproduce in memory. The self is here alone in all its fallibility.

I have heard a very truth-loving person say that if he had ever told the same story ten times he always became doubtful whether he was telling it rightly. You may do well to remember this when you are telling cases. You know the game in which a story is handed on through ten or more persons, and then there appears very little likeness between that told by the first and that told by the tenth. None of them have wilfully changed the facts, but everyone has been a little inaccurate, and the inaccuracies have accumulated. There is some measure of the same difficulty of exact representation of facts by each person's own memory, and we cannot too carefully guard against it. Inaccuracy, it has often been said, has done more harm than falsehood has; and this is certainly true in our own sciences.

Now there can be no better safeguard against these mischiefs than the habit of making studious and careful records of the things that you observe. It should be a constant habit of student life. It is good to make notes of lectures, but better far to write down descriptions of at least some of your own dissections, and of post-mortem examinations, and of cases; and, let me earnestly add, these records should be made whenever and as completely as they can be while you have before you that which you are to

Digitized by Google

describe, so that you may write down the very facts that you are observing, and may revise them whenever you have a chance in the presence of the same or similar facts. *Ad naturam delineavit* used to be a common inscription on portraits and other such works of art. I wish that *ad naturam scripsit* could more often be justly put upon our scientific records. We ought to be able to have it written on the covers of our note-books, and on all our descriptions of pathological changes; and our records should be full, like finished *ad naturam* portraits made by one who has looked again and again at that which he is painting, not like mere pen-and-ink sketches made after a glance or two and then swiftly put in.

I hope I shall not make your future studies seem utterly hateful to you by thus speaking of them as if they were only full of pitfalls and occasions of mischievous error. Really there are none that you may not avoid; but you cannot be too cautious; so I shall continue my advice, for most of us need to be still more careful when in our studies we pass, as we always do, from observing to thinking, and to what we believe to be reasoning. John Hunter, it is reported, used to say to those who would draw conclusions rather than search for facts, "Don't think; try." Happily for science he often did not observe the rule; he was one of the very few who could really sometimes think a truth far beyond that which could be observed; but we are not all like him, and for all of us the saying is an excellent one, "Don't think; try." Do not suppose that you can safely think what must follow from what you know; try whether it is so. Do not think that you can safely explain what you observe by any hypothesis or theory; and that having thus explained it, there is no need of studying it further. Collect new facts, and "try" your theory by them; and if the theory and the facts do not agree, stick to the facts; they will accumulate into larger truths. We must have theories, or explanations as they are called, of many of the facts which we observe. We need them to help us to the best ways available for arranging the facts, as we need bookshelves for books; and they are useful for suggestions as to what, and where, and how to search for new facts. But here, or hereabout, should be the limits of their use; and the using of theories for purposes beyond these is full of danger, and often a great hindrance to progress.

As one looks back on the relations between the collection of facts in practice and the explaining of them in accordance with the theories which were in successive times accepted, and which were commonly called "general principles," and regarded as safe guides in the treatment of disease, we may fairly doubt whether the gain or the loss were the greater. You will see that in each successive generation every fact observed in practice was accepted, not merely as a fact, but rather as an illustration of some pathological doctrine of the time. Mercury was, at different times, an antiphlogistic, a depurative, an alterative, and I know not what besides; harmless words if they had not been used as facts; but because it was thought, not known, to be all these and more, it was so misused and did so much harm that it nearly lost all its just repute, and many disused it. Similarly, bleeding was practised in excess, not so much because of the good it sometimes did, as because the physiology of the time seemed to prove that it must be useful in a large number of conditions in which it was not. And because this was deemed sure, men overlooked the evidence that it was often useless and sometimes mischievous; they did not observe; they preferred thinking, and they thought erroneously, and were guided by their thoughts more than by the facts. Now, these were errors of men as honest and as clear-headed as any in our own day, and among them were some to whom medicine owes great help to progress. Surely, it should make us very cautious. I have cited old historic errors, but exactly similar modes of thinking are everywhere prevalent, exactly similar fallacies in letting doctrines rather than facts serve as our guides in practice. And we need the more caution because this assumed power of explanation is so much more attractive than the gathering of facts. The explanations are so much more our own; like very parts of ourselves; so much more impressive; they sound so learned, patients admire them; some, I have often thought, would rather have their maladies explained than have them cured.

I feel, again, that it may seem as if I thought of you all as entering on a course of study in which there would be only the misery of doubts and failures. It will not be all this. With due caution there may be great happiness as well as great utility in a life full of scientific observation. But it is impossible not to feel in oneself and to see in others how great is the risk of error, how great the risk of utter waste of time in anything but careful study; not to see how an error once begun becomes much more dangerous when we put thoughts into words; and then the words, as if with right, assume the force of facts, and then become guides to ourselves and others, even when we have the care of human lives entrusted to us. And, too surely, the further men pursuing scientific knowledge go from facts, the wider and the pleasanter become the ways of error to those who do not watch and guard every step they take. It is not in the religious life alone that the allegory of the ways is true; equally in science "straight is the gate and narrow the way that leadeth unto" truth, "and few there be that find it." In both alike he that will may find the way; and in both alike he may do well to remember a saying of Faraday, who lived, with equal earnestness, both the religious and the scientific life. Faraday said: "The education which I advocate has for its first and last steps humility."

I said just now "he that will"; I have spoken of the methods of scientific study, of its machinery; but, it may be asked, what is to be the force? what the driving power? It must be each man's will, by whatever motive stirred; when the will is wanting the most perfect scheme is useless; and let me take a privilege of age, and say to the much younger who are here as students that this will must be used and cultivated now, and from first to last, and that the will is even much more important at first than at last; for at last will becomes habit, as certainly for mental as it does for muscular uses. You know this well enough, for every exercise of the limbs, for every kind of athletic dexterity; the movements which required at first the constant force and direction of your will become at last so easy that you are scarcely conscious that the will is engaged in them. It is nearly the same with mental work; but for this, equally or even more, the will must be rightly and earnestly exercised during the whole of student life. Such as the student is, such will be the practitioner.

I have put in print an anecdote of Mr. Abernethy which bears on this; and let me say he ought to be remembered not as a rough wit or a mere eccentric, but as a man of rare sagacity, an admirable surgeon and teacher, and one of the most graceful scientific writers of his time. Entering his lecture-room at the beginning of a session, he looked round at the crowd of students and said solemnly, "Good God! what will become of you all?" Many years afterwards I tried to find an answer to such a question; tried in the dullest way—by statistics. I traced the careers of a thousand of my pupils. I need not give the numerical results; but the general and certain rule was as I have said: such as the student had been, such was the practitioner. There were some few exceptions, but the general rule was clear; and so you may be sure it always will be. So, if you are to be hard-working scientific practitioners, as I hope you will be, you must be hard-working scientific students; you must be always learning for yourselves; always observing, recording, collecting truths; searching for new truths as well as accepting those which you will be told by your teachers. And let me say again and again this will be the best way by which you may become as good practitioners as you possibly can be, and may go on in practice constantly becoming better and constantly acquiring fresh knowledge for others as well as for yourselves.

Often when I have been urging these things I have been told that in ordinary practice there is no time for observing or recording anything useful for science; and that, even if there were time for it, the cases are such as cannot be usefully studied.

Well, as to time, I hope you may all be overwhelmed with practice, and then you will be able to illustrate what I believe is usually true, that none find so much time to spare as they that have too much to do and do it with all their might. And as for the cases, I must admit that a very large number of the cases in private practice cannot be studied minutely or fully enough to yield useful knowledge; and certainly the practitioner may often look with envy on the physiologist, who can choose his study wherever novelties are most nearly within reach, and the renown of discovery may most easily be gained. Still, if there be only a mind for the work, any sort of practice will supply materials; science is possible anywhere and everywhere, even in small country practices. There are evidences enough of this around us; or, if great examples are needed, Jenner was in such a practice when he discovered vaccination, and

Digitized by Google

it was no chance discovery, but the outcome of very careful analytic observations. Koch was a country practitioner in Silesia when he first showed the plant-nature of a specific morbid poison. Mayer was a poor country practitioner when he began his marvellous work on the correlation of forces; and nine-tenths of the honour due for the discovery of anæsthetics must be assigned to ordinary dentists, who worked without knowing it after a sort of scientific fashion. But you need not be ambitious for discoveries equal to those. Good will be done both to yourselves and to others by the observation and careful record of single rare cases or groups of cases of almost any kind, for literally nothing that is published is now lost.

I need not speak of the radiation of knowledge from scientific centres, such as you have here; it is diffused as far every year in all such meetings as those of the British Medical Association and of its numerous branches; further still, it is carried on and on by our medical journals; and from these, those admirable helpers of all good progress, the index-makers, with my friend Dr. Billings for their chief, and with Dr. Neale among ourselves, bring everything within orderly arrangement for those who will wisely search books as well as nature.

But, indeed, there are much larger subjects for which general practice, such as, I suppose, most of you will be engaged in, offers by far the best opportunities for study. Take, for instance, that of the inheritance of disease, than which there is scarcely one more important, either in daily practice or in the profoundest questions of pathology. Facts are wanted for its illustration, which none can supply so well as those who are distinctly family practitioners, and can learn the histories of families. Hospital practice is nearly useless for the study of the inheritance of the most important diseases, and consultation practice is, as I know, scarcely better. If one ventures, in a serious consultation, to ask the relatives of a patient anything about consumption, scrofula, cancer, or even gout, the commonest answer is at once, "Oh, nothing of the kind has ever happened in our family," and the answer is often given as if one had suggested suspicions about the family respectability, as if one had asked whether the father of the family was really an honest man. The facts are either not known, or they are willingly forgotten; and, in any case, negative statements of this kind are nearly valueless. Most persons know what their parents died of or suffered with, and some will tell; but very few can tell much of all their grandparents, and I have only found two who could tell me anything useful about the illnesses or deaths of more than two of their six or eight great-grandparents. Yet from any of these, to say nothing of still more distant ancestors, a tendency to any disease may have been inherited, and may determine the characters of any illness in the inheritor. It is common to see in a person still living a likeness in form or face to the portrait of some remote ancestor; and not rarely it is a likeness which seemed to have been lost in the intermediate generations. But likeness in external features is not more transmissible than are likenesses—whether in shape or in other properties—in any other part: as in liver, stomach, heart, blood, or lungs. We can see the one likeness more easily than the others; but there is no reason or probability that one manner of inheritance should be more frequent or exact than another.

I can see no better hope of gaining facts on these points than by the knowledge which may be gradually acquired by practitioners who, by their personal knowledge, or by record or careful inquiry, can tell what have been the prevalent diseases of members of the same family, or of families intermarrying, during two or three or more generations. Doubtless the knowledge thus gained will be incomplete, but it will be better than any we yet have or are likely to gain by any other means; and its importance in pathology cannot be overstated.

I said just now that negative evidence as to the inheritance of disease is useless; but I should have added that this means only the evidence of patients and their friends. The negative evidence of family practitioners might be very useful; it would be so, for example, if it could tell what proportion of children and of grandchildren do really escape a disease which can be transmitted. Suppose a woman dying with cancer. How many of her children living, say, to sixty will not have it? and how many of her grandchildren? I think I can be nearly sure that on the whole very few would, but no one really knows. It might be ascertained by fathers and sons practising together in places where families are apt to hold firm to their homes.

So, too, observations carefully made in private practice might clear up some questions concerning the mingling of diseases. Suppose, for example, that anyone were asked what are the probabilities of life and health in the members of a family of whose four grandparents one had gout, another cancer, another tuberculosis, another chronic rheumatic arthritis? I know no one who could answer. Yet cases of the kind are not rare, and the questions involved in them are very important for practice, for pathology, for life insurance. Every person may be reckoned as one on whom converge liabilities to the inheritance of any or all the heritable diseases from which his ancestors have suffered. Now, do any of them in their transmission and convergence modify or annihilate one another? Are any mutually exclusive? Unless some such change ensues, it is hard to imagine how our population should increase and maintain its working power. Or, again, are any capable of combining as in an organic compound? and what is that compound? Surely here are questions enough for anyone who in the opportunities of family practice will study them carefully and record them. They are among the many questions that can be settled only by facts, and many of you will have the facts within your reach.

I could easily add to the list of subjects for which the ordinary practice of our profession, whether in families or in hospitals, or dispensaries, whether private or in the public service, offers the best possible opportunities for scientific study. Such are the utilities and adaptations of proposed new medicines, the testing of them with much more than usual doubt and patience; the distribution of disease in reference to soil and other local conditions, and many more. Only learn to study after the right manner, and, as all who have had experience in it will tell you, you will find it a source of very rare happiness and utility, and of no harm whatever. There are some, indeed, who would tell you that the scientific man is ill-fitted for anything but science; that he cannot be punctual, business-like, a plain speaker, pious, or I know not what else. It would be difficult to find greater nonsense in any of the books or journals on a modern book-stall. There is nothing that a man may not be at the same time that he is scientific. I would not make light of anything that would hinder you from being business-like; for I should have to admit that I have known more failures in our profession through want of this quality than from the want of any other; more than from the utterest want of scientific or even of good practical knowledge. But the failures were not only among the scientific. Surely I need not say in Manchester that good men of science may be also good men of business; and what may be seen here may be seen everywhere. If a man of science cannot be business-like, it is the fault of his brain, not of his study; he would have been the same in any other pursuit in life. Devotion to science may be combined with whatever is good or evil; but in our profession its associations with what is good are far more predominant, and it may give a good direction to many mental dispositions which are apt to drift into mischief or to folly or to waste of time. But I need not dwell on these. It will be enough if you will bear in mind its utility for those whose lives and happiness will be committed to your care. As long as you live, the more and the better you study, the more you will know, and the more good you will be able to do; and this good will be of the kind that may be most real—the good not only of lengthening men's lives, but of increasing their working power and their happiness. And this is the better. Time is not the best or only measure of the value of life; for now, as distance may sometimes be best estimated, not by space but by the time required to traverse it, so each life, as to its quantity, should be measured, not by years, but by the work done in it. The good that medicine and surgery may do is not half estimated by bills of mortality that prove only an average greater length of life. More good is done by making a larger part of each life more fit for working; and in this may be a measure of utility such as may be unmatched in any other calling. Herein may be your utility; herein will be your duty; herein your grave responsibility.

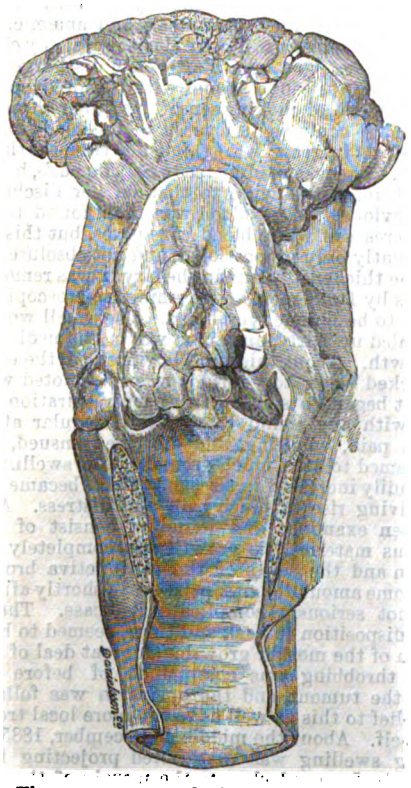
And one word more. We boast of the progress of medicine and surgery in the last fifty years. We try to tell all the good that it has brought to men. In the next fifty, through which I hope you will all live, the gain will be still greater; for the progress of knowledge is with increasing velocity.

Digitized by Google

Now, how much will each of you contribute to this progress? None can tell. But this at least is certain, that you are bound, by plain duty, to do your best to contribute to it largely: even as it is every man's duty to do all the good he can by all the means that can fairly come within his power. And remember always that wherever power is, there is duty; and wherever duty, there responsibility to God and man.

A CASE OF LYMPHOMA AFFECTING THE LARYNX, EYELID, AND CEREBRAL MEMBRANES.

BY E. CLIFFORD BEALE, M.B. CANTAB., M.R.C.P.,
ASSISTANT PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK; PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL.



THE following case illustrates in a remarkable degree the truth of the present views with regard to lymphomata—viz, that they are liable to occur wherever lymphoid tissue is present in the healthy state. The distribution of the overgrowths of lymphoid tissue in this instance was peculiar, but apart from this peculiarity the anatomical character of the tumours was not in any way abnormal. Many of the minor clinical details not directly relevant to the main points of the case have been omitted for the sake of brevity. I am indebted to the kindness of Dr. Bristowe and Dr. Felix Semon for permission to make use of the notes taken under their supervision during the period of the patient's stay in St. Thomas's Hospital.

Mrs. B——, aged forty-one, wife of a builder, a small spare, delicate-looking woman, was seized in May, 1885, with sudden vomiting of large quantities of dark blood, fluid and in clots, which continued more or less during three days. She had been confined nine weeks previously, the labour having been natural and easy, but since that time she had had much swelling about the glands in the neck, a sore throat, and some difficulty in swallowing. It appeared that she had been subject to enlargement of glands about the sterno-mastoid muscles on both sides for the last two years. They had sometimes been more actively swollen on the one side and sometimes on the other, but had occasionally almost entirely subsided. One year ago a smart hæmorrhage had taken place, proceeding, as far as the patient's account indicated, from the tonsils. About the same time she had also had an attack of pleurisy, and possibly pneumonia. Her voice had been decidedly weaker ever since, but had never been quite lost. A slight phthisical taint could be traced in the family history on the mother's side, but the patient's own family of five children were apparently free from any signs of strumous or other constitutional peculiarity. There were no indications upon which to found anything more than a conjectural diagnosis of the origin of the blood. General physical examination disclosed nothing abnormal about the abdomen. The urine was natural. The heart's sounds were feeble, but clear at the apex, a faint systolic murmur being audible in the second left intercostal space. The lungs were quite normal. In the pharynx the left tonsil was greatly enlarged and very pale, feeling hard and lobulated to the touch, and with no evidence of any acute inflammation going on within it. The tongue was generally clean, the bowels constipated as a rule, and the appetite very poor. During the first few weeks after the hæmorrhage the patient gained strength slowly, the tonsil diminished in size, but the glands about the left sterno-mastoid muscle became more swollen and very tender. This condition again subsided, but the patient still remained very feeble and anæmic. On June 30th a certain amount of œdema of the subconjunctival tissue in the right eyelid was noticed, but no cause for it could then be made out. On July 9th the patient had sufficiently recovered strength to admit of the right tonsil being excised. The wound healed well in the ordinary way, and she remained in fairly comfortable health, but still with occasionally enlarged and tender cervical glands, for the next few weeks. Seen again in August, the subconjunctival swelling had considerably increased, the eye being nearly closed; the voice was very feeble and reedy, and there was a troublesome short cough. The glands on the left side of the neck were much reduced, whilst one or two on the opposite side had again increased in size. The larynx was examined for the first time since the extirpation of the tonsil, and it was noted that the epiglottis at its free edge appeared to be normal, but immediately below it and to the left was seen a thickening of the tissues resembling adenoid hypertrophy, and involving the lower part of the left side of the epiglottis, the left ventricular band, and to some extent the left glosso-epiglottic fold. This thickened tissue projected into the larynx, and in its anterior part obstructed the clear view of the left vocal cord. The left arytenoid cartilage was to some extent thickened in the same way, and was nearly if not quite motionless on attempted phonation, the cord itself only showing a very faint attempt at adduction. The patient was at this time seen by Dr. Felix Semon, who attributed the fixation of the left cord to a mechanical, and not to a paralytic cause. Shortly afterwards she was admitted into St. Thomas's Hospital under the care of Dr. Bristowe. During her stay of two months in the hospital no very marked change took place. The swelling of the eyelid increased a little in size, and she complained much of a sensation of pain and pricking in the eyeball. The pulse rate as a rule was high, but there was no rise of temperature. She had no difficulty of breathing or of swallowing, but remained very weak and anæmic. Microscopic examination of the blood did not reveal any changes of importance in it. One month after her discharge from the hospital she was seized at times with fits of dyspnœa, and complained much of choking sensations in her throat, but no definite change could be discovered in its condition, except perhaps a slight increase in the thickened tissue at the back of the tongue. She was readmitted to St. Thomas's, her general condition being very similar to that on her discharge two months previously. The blood was then found to contain a slight increase of white blood-corpuscles, but this increase was apparently only proportional, and not absolute. A small piece of the thickened tissue in the larynx was removed with the forceps by Dr. Semon, and examined microscopically. It was found to be simple lymphoma. The small wound thus caused healed up fairly, and there was no immediate return of the growth. About this time, however, till the end of the case a marked inspiratory stridor was to be noted whenever the patient began to speak. Ordinary respiration was not attended with any sound whatever. Irregular attacks of abdominal pain, vomiting, and diarrhœa ensued, and the patient seemed to lose much ground. The swelling of the eyelid steadily increased in size, and the lid became partially everted, giving rise to much pain and distress. A portion having been examined and found to consist of lympho-sarcomatous material, the growth was completely removed by excision and the edges of the conjunctiva brought together. Some amount of erysipelas set in shortly afterwards, but did not seriously complicate the case. The wound showed a disposition to heal, and there seemed to be hardly any return of the morbid growth. A great deal of occipital pain and throbbing was complained of before the removal of the tumour, and the operation was followed by marked relief to this as well as to the more local troubles in the eye itself. About the middle of December, 1885, a small fluctuating swelling was first noted projecting from the middle of the forehead close to the margin of the hair. In other respects the patient remained in about the same condition. In January, 1886, she was subject to several short attacks of faintness and vomiting, without any manifest cause. The frontal tumour increased in size, but was neither red nor tender; being very soft and fluctuating, it was explored with a capillary needle; but no fluid was withdrawn. It gave rise to very little discomfort, the patient only complaining that it ached sometimes. Until the middle of March the patient maintained strength, and seemed to improve; but after that time, without any obvious cause, she suddenly gave way, became rapidly prostrate, could take no food, and died, exhausted and unconscious, on March 21st.

Owing to unavoidable delays no post-mortem examination could be made until the fourth day, when the decomposition was very far advanced (the coffin had already been closed on that account). The tumour on the forehead was found to be a large lymphomatous growth from the under-surface of the dura mater, which had eaten its way completely through the skull, an opening with ragged edges being left in the frontal bone 4½ in. by 3½ in. in extent. The brain beneath, though much compressed, was healthy. In the neck were several masses of more or less indurated glands, some of

Digitized by Google

them reduced to hard and almost fibrous material, others being soft and fleshy, but none of them caseous or disintegrated. There was no sign of any fresh enlargement of the tonsils, but the base of the tongue and the left glosso-epiglottic fold were much thickened by infiltration with lymphomatous material. The epiglottis also was thickened and infiltrated on its laryngeal side, the new material having a thickness of a third of an inch below the cushion of the epiglottis. Its free edge, however, was normal. The growth on the left side extended a little over the vocal cord, overlapping it, especially in the anterior third, but not in any way attacking the cord itself. The lymphomatous material, in fact, was limited to those parts in which adenoid tissue normally exists, and was most abundant in and about the ventricle. The swelling thus formed (as will be seen in the annexed woodcut) was not uniformly smooth, but divided by deep and irregular sulci, extending in places almost as far back as to the cartilage. Examined by the microscope, both this tumour and the one on the scalp were found to consist of small-celled tissue, loosely held together by a fine stroma (so loosely as hardly to be coherent in thin sections), and traversed by fibrous septa in places. The bloodvessels in it were small, few, and far

between. There was no marked enlargement of lymphatic glands elsewhere, with the exception of two masses of apparently glandular tissue, much decomposed, close to the spleen. Owing to the condition of the parts their exact relation could not be made out. The stomach and liver were normal, and no source of hæmorrhage could be discovered. The spleen was much decomposed, but not enlarged.

The chief points of interest in this case centre round the singularly abnormal distribution of the adenoid overgrowth. Few, if any, cases are on record of lymphoma affecting the interior of the larynx, and such growths in the eyelid and cerebral membranes are only mentioned in works upon the subject as of possible occurrence. The case, as a whole, may be classed as one of Hodgkin's disease, beginning, as it did, with a chronic affection of the cervical glands, gradually followed by hypertrophy of adenoid tissue in other parts. The clinical history of the disease differs considerably in different cases, its course being sometimes much more rapid and in others much more protracted than in the present instance, in which there would seem to have been a double process going on at intervals, one group of glands being subject to active hypertrophy whilst another was undergoing precisely the opposite change, the whole set occasionally subsiding to almost their normal proportions. The secondary growths also differed considerably in their activity. The frontal growth was rapidly progressive from its first appearance; the palpebral swelling, though steadily progressive, made a much slower advance; whilst that in the larynx remained almost stationary from the time when it was first diagnosed. It should be noted that the operative procedures, both in the eyelid and in the larynx, were quite successful as far as they went, and gave real relief to the patient, and that neither was followed by any return of the growth or by increased activity of the remainder of it. Although removal of swollen glands under these circumstances is forbidden in most of the text-books of surgery, except in cases of dire necessity, it is probable that much temporary relief to pain or even discomfort might be given by operative measures, when the other features of the case point, as in the present instance, to a decided tendency to recovery on the part of the patient. In the more rapid cases the rule of non-interference is no doubt the best, but in the more chronic cases there is often good reason to suppose that the duration of life would be considerably prolonged thereby and the suffering of the patient materially lessened. In the present case there was no very marked anæmia, the blood only showing a comparatively small diminution in the number of red corpuscles, nor was there the tendency to hæmorrhage which is frequently observed in such cases, although the patient was subject to several small surgical procedures involving some degree of bleeding. The painless course of the frontal tumour, eating its way slowly through the frontal bone and giving rise to no more serious symptom than occasional aching, was by no means in accordance with ordinary experience. The pressure upon the brain beneath, although very considerable in extent, was not marked by any positive symptoms, unless the few attacks of faintness and vomiting from which she suffered during the last few months, can be attributed to it. The case therefore forms somewhat of a pathological curiosity, and, as far as the laryngeal part of it is concerned, a decided rarity, but it may have some bearing upon practical treatment, as showing that free removal of such tumours may afford for a time the greatest local and general relief, even when undertaken, in defiance of the ruling text-books of surgery, under circumstances which are not of themselves sufficiently grave to threaten the life of the patient.

Upper Berkeley-street, W.

NOTES OF A CASE OF HEPATIC ABSCESS BURSTING INTO BOWEL; RECOVERY.

BY HUBERT A. BURKE,
SURGEON, ROYAL NAVY.

G. J——, aged thirty-four, carpenter, complained first of feeling ill on Feb. 7th, 1887, on board H.M.S. *Orion* at Alexandria. The progress of the case is as follows:—

Feb. 7th: Headache for two or three days. Bowels open by purgatives. Pain in abdomen, over hepatic region. Liver chiefly enlarged, and spleen also. Pulse 88; temperature 99·8°; evening temperature 102°, 102·4°, 101·8°. Ordered diaphoretic mixture three times a day.—8th: temperature 100·8°. Tongue furred. Pain at epigastrium on pressure. No sickness. Pulse 80; temperature 102·2°, 101·6°, 101·6°. Twenty grains of quinine ordered.—9th: Bowels constipated. To have an ounce of castor oil. Temperature 100·2°, 100·2°, 100·4°.—10th: Bowels open three times. Tongue cleaner. Still pain in epigastrium. Cannot sleep. Ordered fifteen grains of quinine. Temperature 101°. Tongue furred. Great tenderness at epigastrium. Poultice to be applied to abdomen. A mixture composed of dilute hydrocyanic acid (five minims) and aromatic spirit of ammonia (one drachm), in an ounce of water, to be taken immediately.—11th: Temperature 98·8°. Still pain at epigastrium. Tongue very furred. Bowels confined. Ordered an ounce and a half of castor oil.—12th (noon): Tongue cleaner. Bowels well open. Pain in epigastrium diminished. Pulse 72; temperature 100°. The acid mixture with gentian (one ounce) to be taken three times a day.—13th: Temperature 99·2°. Some pain in epigastrium at one spot. Ordered ten grains of

Digitized by Google

sulphate of quinine. - 14th: Temperature 98·6°. Better. Pulse 85. Tongue cleaner. Bowels confined. — 15th: Temperature 98·8°. Bowels not open for three days. To take an ounce of castor oil; also a drachm of hydrocyanic acid mixture three times a day. Evening temperature 99°, 100·6° — 16th (noon): Still pain in epigastrium. Bowels well open. — 17th (noon): Better.—18th (noon): Pain in epigastrium diminished. — 19th (noon): Bowels confined. Ordered a black draught.—20th: Bowels well open. Patient has lost flesh a little. Appetite poor. Has been fed on soups, chicken, rice-pudding, and milk.—25th: Still pain in epigastrium, but general condition improved; so he returned to duty.

This case was considered as one of constipation and dyspepsia, and treated as such. When he went to duty, he still complained of the pain at the epigastrium, and whilst at work he had on many occasions to apply for a purgative, as he always for years had suffered from constipation. He slept fairly well until March 27th, 1887, when he again presented himself to me for treatment.

March 27th: Temperature 101·6°; pulse 110. Skin moist. Complains of great pain in the abdomen. Breath very fetid. Bowels open once after taking a black draught. The following mixture ordered: dilute hydrocyanic acid, five minims; aromatic spirits of ammonia, ten minims; chloric ether, fifteen minims; water, one ounce: three doses.—28th: Temperature 99·6°. Bowels not freely open. To take an ounce of castor oil. Breath still fetid. Low diet. Evening temperature 100°, 100·2°, 100·6°. Still pain in epigastrium, but better than yesterday.—29th: Bowels open; scybala; very fetid. Pain at epigastrium. To apply a mustard plaster to abdomen. Temperature 100·2°.—30th: Temperature 99·6°. On examining the abdomen, there is a hard swelling over the liver, which is circumscribed. No sign of fluctuation to the right of the mesial line of the abdomen below the ribs. Extent ½ in. by 2 in. There is pain on pressure. The general health of the patient is good. He likes his food well. Can lie only on his back. Tongue very foul. Percussion over tumour is dull. Slight bulging of the ribs on right side. Pain on respiration. Short dry cough. Unable to sleep at night. Twenty-five minims of hydrochlorate of morphia to be taken at night. Temperature 100·2°. Bowels constipated. Podophyllin pill (quarter of a grain) given. Bowels open three times; motions very fetid; loose biliary matter, with lumps of hard fæcal matter.—31st: Temperature 99·2°. Swelling very distinct; very prominent when the patient stands up; conical in shape. Liver enlarged. Complains of great pain. Fomentations applied. To take an ounce of acid and gentian mixture three times a day, also to have four ounces of port wine. Restless at night. Repeat morphia.—April 1st: Temperature 99·4°. Swelling larger; hard; no fluctuation; distinct edge around it; pain on pressure; dimensions of whole circumscribed tumour 4½ in. by 3¾ in. Abdomen distended; abdominal veins enlarged. Patient was sick once (bilious matter). Is losing flesh rapidly. Expression of face anxious. Weight of patient 140 lb. Tumour is adhering to abdominal wall, but very slightly. Can lie only on his back; much pain and dragging if he stands up. Bowels not open. Ordered a soap enema. Evening temperature 99·8°, 100·4°, 101°. Ordered low diet, with port wine; also to take acid and gentian as before.—2nd: Temperature 99·6°. Passed a fair night after morphia. Pulse small and weak. Abdomen less distended, as the bowels were well open; had large evacuation of hard fæces, with biliary matter. No sign of fluctuation in tumour, which is getting more conical. Appetite fair. Evening temperature 100·8°. — 3rd: Temperature 99·8°. Swelling in abdomen increased in size downwards. Pulse quick, small. Skin hot. Tongue cleaner. Sleeps after morphia. Distension of abdomen smaller. Evening temperature 101°. Swelling inclined to point in abdominal wall. Skin slightly red. Frequent poultices have been applied to the swelling. Some sense of fluctuation. Ordered a turpentine enema.—4th: Temperature 100°; pulse 104. A very large quantity of scybala, hard and black, evacuated. Swelling now extends to umbilicus; is larger, measuring 5 in. by 4 in. Distension of abdomen gone. Patient says he feels much easier. Urine acid, containing bile, but no albumen. To repeat poultice. Six ounces of wine to be given. Patient is getting very thin; face drawn; expression very anxious.—5th: Temperature 99°. To repeat enema. A large quantity of scybala came away, with some mucus. Swelling more prominent in abdomen; soft; distinct fluctuation; extends upwards to xiphoid cartilage; feels soft in the centre, but hard all round. Urine clearer; contains biliary matter. Repeat poultice.—7th: Soap enema given; a small quantity only retained. Bowels open; motion consisting of small hard lumps of fæcal matter, with a little mucus. 10.20 A.M.: Bowels open again; a large quantity of pus passed, mixed with blood, and having a fetid smell; this gave instant relief to the patient. Swelling soft at one point of abdomen; pits on pressure; slightly glazed; dull on percussion. Six ounces of brandy given. 1 P.M.: Bowels open; more pus and blood passed; at stool twenty minutes; two pints of contents; pan contains urine, a small amount of fæcal matter, and a large quantity of pus and blood. Tumour smaller. Patient is very much relaxed. Temperature 98·6°; pulse 130. Anxious expression of face is gone. Patient much emaciated and very weak from frequent purgation, but is bright and more cheerful. To have six ounces of wine, also soup, milk, &c. Has lost much flesh during the last three days. Ordered half a grain of opium powder, a grain and a half of extract of belladonna, with a sufficient quantity of extract of gentian, every three hours.—7th (noon): Still the same faint sign of fluctuation in swelling, which is much smaller. General condition of patient greatly improved. Takes food well. Not sick. During the last few days the skin has had a slight icteric tinge, also the conjunctivæ. To repeat opium and belladonna; and six ounces of wine to be given. Pulse 104; temperature 99·4°, 100·4°; 100°.—8th (noon): Pulse 124; systolic murmur at apex, probably anæmic. Swelling much diminished; no fluctuation. Bowels open; fæcal matter more normal; some pus and blood.—9th (noon): Doing well.—10th (noon): Better. Swelling very much smaller.—11th (noon): No pain over swelling. Pulse 130. Bowels confined; an ounce of castor oil to be given.—12th: Bowels well open; some pus, but very small amount. Patient better and more cheerful.—13th (noon): Got up to-day for the first time. Diet to be chicken broth with wine. Tonic medicine ordered.—14th (noon): Swelling disappearing. General health good. Bowels confined; castor oil to be taken.—15th (noon): Bowels open.—16th (noon): Swelling smaller and hard. Patient continued to improve in every way; gained flesh and appetite, and the swelling gradually disappeared. On May 1st he went to duty. On April 29th his weight was 146 lb., and on May 31st 155 lb., when there was no sign of the tumour, but merely a feeling of hardness over the part where the tumour had existed.

Patient's previous history.—Has never had any sickness before; no symptom of dysentery at any time. He is well developed. Has not been temperate in drink and has always eaten in large quantities. He has been thirteen years in the navy. He has served only in the Mediterranean, and is now serving at a China station.

Remarks.—The man left Alexandria for Singapore on March 17th and reached here on April 26th, so that he was ill during the whole voyage. Temperature in the sick bay was from 90° to over 100° F.; we had no ice or milk, and everything was against the patient's recovery. The patient came to me on June 6th suffering again from intense pain over the liver, which was evidently a return of his former trouble, and I invalided him home; but the hopes for his ultimate recovery are very small.

Singapore.

ON THE HÆMO-DYNAMICS AND TREATMENT OF CEREBRAL HÆMORRHAGE.

BY LEONARD BRADDON, F.R.C.S.

Is there any situation more hopelessly depressing than the attitude of the physician by the bedside of a severe case of cerebral hæmorrhage? So certain of the diagnosis that he seems able to view the fatal clot through the very skull, perfectly acquainted with the antecedent pathology and the actual mode of operation of the silent force that, as it leaks, destroys, he yet stands helplessly by, the author only of trivial directions, utterances apathetically oracular. From the days of darkness until now no vigorous attempt seems to have been made to deal rationally with an accident that sweeps away thousands of active lives, and the routine of treatment invariably adopted might be designated insignificant, if it were not probably actually injurious. "*Post sanguinis missionem, si non redit motus et mens,*" Celsus wrote,

Digitized by Google

"*nihil spei superest.*" This treatment has, after long ages, been discarded; the three last words, however, seem to be impressed upon the profession with all the indelibleness of despair. In this short article I am neither about to attempt to add to the already clear pathology of the question, nor to recapitulate cases and symptoms; but I wish to draw the attention of the profession to certain aspects of the lesion, which, if they have been before studied, have been since neglected, and which afford, as I believe, grounds for the adoption of strong and, there is every hope, successful methods of treatment.

At the post-mortem table the most striking feature in a fatal apoplexy is the comparatively enormous amount of blood poured out and the force which has been liberated. The grey and white matter is ploughed up in all directions, commissures are burst through, and often smaller vessels torn across. Dr. Wilks says the weight of the clot is commonly 3½ oz.,[1] and from these considerations infers that the vessel must be of great magnitude in such cases. But apart from the fact that the miliary aneurysms of Charcot and Bouchard, the most frequent sources of hæmorrhages, are formed on, usually, the smaller twigs, none of the vessels entering the brain substance are of any magnitude; those from which bleeding has been shown to have occurred have been secondary branches of these; and, inasmuch as it is hardly possible for an artery to be torn completely across, in all cases the seat of leakage must be a hole of very inconsiderable diameter. How, then, is such tremendous force exerted that the extravasation can overcome the resistance of the brain substance, which in a fresh brain exposed to a stream of water is evidently considerable, and in a situation where it is uniformly supported by unyielding walls on all sides must be much more?

When a trephine hole is made in the calvaria and the dura is cut, the brain always bulges slightly into the aperture; at any rate, it never shrinks downward on exposure. This shows, and tracings from the fontanelle and from accidentally exposed brains support the view, that the pressure within the skull is certainly not negative; it is probably a good many millimetres positive, although I know of no exact data on the subject. The extravasation then occurs from an arteriole where the pressure cannot be more than, say, ten millimetres, into tissue confined at certainly an atmospheric pressure; and into this tissue it is extruded to the extent of some ounces, an amount which must considerably add to the condensation of the brain substance and the total intra-calvarian tension. Some estimate of the force exerted may be gained from the flattened aspect which, in severe cases, the convolutions frequently present. By artificially effecting such flattening on a fresh healthy brain it might be possible to reduce such an idea to figures, but I have had no opportunity of doing so. However, the pressure happens and has to be accounted for. It is, in fact, a problem in hydro-dynamics. The first drop, outside the first small rupture, represents, in fact, a miniature but perfectly complete hydraulic press—a "hæmostatic" paradox. Surrounded on all sides by solid, communicating with a small tube, in which the heart-beat works like a piston, every impulse in the arteriole increases the extravasation (perhaps widens the inlet); the total pressure in the arteriole at the seat of rupture is multiplied in increasing dimensions by the area of the extravasation, the force of which is exerted in all directions equally. Thus each heart beat, like the force-pump, increases the quantity of fluid in the hydraulic chamber and the destroying force of the extravasation—only the safety valve is a long way down, at the aortic valves. [One would thus *a priori* assert it to be impossible for cerebral hæmorrhage to occur in a case of aortic regurgitation, so perfect is the analogy.] When the pressure in the bleeding leak is multiplied by the superficial area of even a moderate hæmorrhage, it is easily seen that the force exerted by the latter is very great. Supposing a hæmorrhage of 10 mm. in diameter, and a tension in the arteriole of 10 mm., the total extravasating force would be $(10 \times \pi\rho^3 =)$ 3750 mm., or about five atmospheres. These figures may be exaggerated, but they are not probably far wrong. Of course it would not take five atmospheres to tear apart brain tissue *outside*, but within the calvaria the resistance to rupture must be considerably greater. In any event, it is evident (1) that the destructive effect of an intra-cerebral hæmorrhage is due to the hydraulic force of the leakage; (2) that as the disruptive power increases in hydrostatic ratio, every second of time is of paramount importance in treatment; (3) lastly, that there is a hopeful method of treatment.

If the views suggested above are correct, every hæmorrhage into the brain unchecked ought to be, it may be said, inevitably fatal. I believe it to be only an accident, contingent on the manner merely of rupture, that every hæmorrhage into the brain from an arteriole little smaller than one of the perforating arteries is not invariably fatal. But one can imagine that (1) the sources of the smaller hæmorrhages are capillary vessels; (2) that in the case of miliary aneurysms, the redundancy of tissue, and in other ruptures fragments of tissue, or clot, may act in a valve-like manner to prevent further leakage; (3) the tendency to early clotting dependent on general (and perhaps unknown local) conditions is, in cerebral as in any other hæmorrhages, the greatest check and natural safeguard against further bleeding.

Assuming, then, the truth of the theory as to the production of the spreading force of the hæmorrhage, the problems of treatment are how to check a commencing, and how to relieve the symptoms due to a large established, extravasation. Inasmuch as every heart beat is a hydrodynamic force fraught with danger, every pulse restrained is treatment for success. Since blood pressure means blood extravasation, every remedy that will lower it will increase the chances of recovery. On these grounds, it seems that text-books and physicians have all for generations erred alike. The patient is generally directed to be laid low; to be kept cool, or even cold externally; to be fed on little, and nothing warm. Drugs, save purgatives, are decried; narcotics are especially condemned. Now, the horizontal posture, if it lower the frequency of the heart beat, increases the blood pressure within the cranium, the outflow from which gravity, best brought to bear in an upright attitude, especially assists. Cold externally means congestion inside. Starvation and cold food mean foregoing the immense advantage of attracting as much blood as possible to the portal system, and so lowering the supply elsewhere. Narcotics producing sleep, during which the brain is anæmic, could not be certainly injurious; and although of doubtful utility in the presence of better drugs, in their absence opium ought not to be despised; it lowers the blood pressure and relieves the brain. As regards purgatives, they are an open question. Trousseau, in his graphic lectures, alone, so far as I know, has adopted such a plan. He makes his patients sit up, take food, and, if possible, exercise. More important than all in medical treatment should be drugs which lower the blood tension. In nitrite of amyl, nitrites generally, pilocarpine, and other tension-decreasing remedies, we have powerful means of treatment. Warmth to the hypogastrium and the hot bath act similarly. But the simplest, the most potent, the most readily applicable, and yet most ignored remedy of all lies in surgical resource. The lesion consists in hæmorrhage from a distant and unreachable source; the remedy, therefore, is to cut off the blood supply by applying pressure to the nearest main trunk. If the seat of the hæmorrhage is diagnosed, the carotid ought to be immediately compressed upon that side, and the pressure should be kept up for several hours in order to give the ruptured artery time to become obstructed by the formation of a clot. In any case, upon the first symptom of hæmorrhage, this operation should be had recourse to instantaneously. That, if this were done in all cases at the first onset, many grave and fatal hæmorrhages would be checked, I have no manner of doubt. From time to time the pressure might, after the first three hours of continuous application, be omitted, and observation be made whether the symptoms of bleeding continued. If it is impossible to diagnose the side of the lesion, both carotids might, in grave cases, be compressed. If continued pressure cannot be applied efficiently, the carotid ought to be tied. This procedure can of course only completely arrest the bleeding where it proceeds from a branch of the external carotid—i.e., is extra-meningeal. But, in spite of the circle of Willis, it must obviously greatly diminish the force of blood-flow from intra-cerebral vessels, of which there is indeed abundant clinical evidence.

Two or three years ago, when dresser to Mr. Howse, in a case of extra-meningeal hæmorrhage for which he trephined, and in which, after turning out the clot, the bleeding could not be checked, I suggested compression of the carotid with the direct intention of checking it by this means, and

[1] Wilks and Moxon, Path. Anat., p. 229.

Digitized by Google

Mr. Howse approved of the suggestion. In that case I kept up, with his approval, constant pressure for three hours, with the result of arresting the bleeding; and this did not recur. The artery ruptured in this case was evidently of large size, judging from the stream sent out through the trephine aperture. Mr. Howse afterwards reported the case at, I think, the Clinical Society: and subsequently Mr. Charters Symonds, in a paper on the Treatment of Extra-meningeal Hæmorrhage, referred to this case, and advocated compression or ligature for arresting uncontrollable bleeding. But I do not know to whom they credited the original suggestion. It is possible, of course, although not recommended in text-books or known generally, that the plan is by no means novel. However, it is a valuable, the only valuable, resource in cases of beginning intra-cerebral hæmorrhage.

The greater problem remains: Is there any treatment worthy of the name for those more severe and so frequently fatal cases to which one is called, to find a comatose patient breathing stertorously and slow, with dilated pupils and a burdened pulse, with distorted features and turgid veins, with rigid or relaxed or convulsive and twitching limbs, and absent reflexes—with, in fact, any or all of the symptoms which indicate a severe and progressing extravasation within the brain? If the side can be diagnosed, the carotid can still be compressed and the hæmorrhage arrested; but what then? With three or four ounces of blood distending the brain substance, and drowning vitality by mechanical pressure, what is to be done? In many cases, without treatment a speedy fatal issue is obvious, and in such any plan which offers a ray of hope is justifiable. Trousseau, in defending his rejection of the bleeding plan in such cases, compares the clot to a foreign body, which cannot be affected by such measures. His analogy is good; but the general implication is not correct. It is not because extravasated blood is a foreign body that cerebral hæmorrhage kills. In the extra-meningeal case of Mr. Howse already referred to (and which I may be allowed to quote since he has published it), upon removing the bone the symptoms were immediately alleviated, the pulse falling, the dilated pupils contracting, the respiration quickening, the convulsions and rigidity (on opposite sides) ceasing. In a similar case reported in THE LANCET (August 20th) the same thing is noted. Immediate relief follows the removal of the bone, and consequent diminution of pressure. It is, in the graver cases, not only the shock, the diffuse effect of the local lesion, but still more the mechanical pressure of the hæmorrhage, that kills. The nerve centres essential to life are not directly bruised, but the great intra-cranial pressure evidently crushes out their vitality by direct vital interference. Tumours, hydrocephalus, abscesses, act similarly; their pressure destroys. Now, if there be any, ever so small, an opening in the hydraulic press, the hydrostatic paradox is destroyed; and if an opening were made into these cerebral hæmorrhages, at least one avenue to death, that by mechanical pressure, would be barred. There is plenty of evidence in apoplectic cysts, chalky abscesses, cured hydrocephalus, and pachymeningitis to show that extravasations which have not killed by pressure may be absorbed in the brain as elsewhere. And in these days of cleanly surgery meningitis need not be feared. Hence it is no heroic surgery to propose that in a case of bleeding, very grave or tending clearly to a fatal issue, the calvaria should be trephined, and a trocar or bistoury or probe plunged into the brain substance to reach the outpoured mass of blood. A way thus opened for its escape, it is probable that some of it would be gradually extruded; at any rate the intra-cranial pressure would be thus relieved; and with the application of a sitting posture, the use of nitrites, compression of the carotid, and the other measures advocated for checking further bleeding, one may hope for a successful issue to the treatment of this, one of the most fatal and hitherto the most hopeless of all the assaults by which death essays to vanquish the human stronghold.

Upton-on-Severn, Worcestershire.

A CURE FOR MALINGERING.—Some members of a Dresden workmen's benefit society, having gone on the sick list on account of pains of a character that could not be diagnosed by the surgeon, and of alleged inability to use the arm as required for their work, were ordered by the club to attend at the factory where they were employed, to sit on a bench during the whole of the working hours, and to look at the men at work. Scarcely any of them held out for more than a week.

SOME REMARKS
ON THE
KIND OF SPLINT MOST AVAILABLE FOR GUNSHOT FRACTURE OF THE LOWER LIMBS
ON THE FIELD IN CONNEXION WITH TRANSPORTATION.[1]

BY R. F. TOBIN, F.R.C.S.I.,
HON. BRIGADE SURGEON, ARMY MEDICAL STAFF; LATE ASSISTANT PROFESSOR OF SURGERY, ARMY MEDICAL SCHOOL, NETLEY.

MY remarks have reference chiefly to gunshot fractures of the hip and the upper third of the femur; and as whoever has had practical experience of the difficulty of giving to such injuries during transport and subsequent treatment that essential condition to recovery—rest—will gladly welcome any suggestion on this subject that may even in a slight degree be helpful, I shall make no apology for occupying attention during a very brief period.

An appliance that will give rest to a fracture in the locality indicated must fix not only the injured limb, but also its fellow and the trunk as far as the thorax. For it is plain that, if the sound leg is left free, the patient will try from time to time to ease his position by means of it, and so tilt the pelvis and disturb the fractured parts; and that even a still greater amount of disturbance will occur if action of the psoas and iliacus muscles is permitted by the movements of the pelvis and lower half of the spine being left unrestrained. It also seems to me desirable that the appliance selected should fix the injured part by being placed behind it, rather than in front or at one side. A Liston's or a Bryant's splint gives immobility as long as it is supplemented by the patient's bed, but, as far as my experience goes, no splint on which the limb does not rest by its own weight, gives satisfactory support when for any purpose the patient has to be lifted. The foregoing conditions are fulfilled by the splint to which Mr. Thomas of Liverpool has given his name, and by that of Mr. Fagan of Belfast, which was brought to the notice of this Section during the Congress of 1881. To the general employment of these on the field, the difficulty of fitting the one and the costliness of the other are obstacles—obstacles not insurmountable, and which, as the instruments are most useful ones, will, I hope, be overcome. In the meantime, let me bring to notice the following appliance, which affords rest and support in a somewhat similar manner, but by means of materials more available on active service. The patient having arrived at the dressing station, where, by whatever name it may be known in different countries, the wounded first undergo a thorough examination, and it having been decided to make an attempt to save a limb fractured as described, I would proceed as follows: Having treated and dressed the wound after the fashion in vogue for wounds in general, the canvas of a stretcher with removable poles is spread upon the ground, and is cut transversely into two about its centre. The following materials are also made ready: (1) Two pairs of trowsers—viz., that of the wounded man and any other obtainable of about the same size; (2) a few strips of blanketing or a few large towels or other material, of a size to go as a binder round the waist and hips in three or four layers; (3) one stone and a half of plaster-of-Paris; (4) three gallons of water; (5) a bucket or other receptacle in which to mix the plaster and water; (6) three yards of calico torn into three many-tailed bandages; and (7) a roll of cotton wadding. The plaster is mixed with about an equal quantity by measure of water, and into the creamy fluid so formed the two pairs of trowsers and the material that is to go round the waist and hips as a binder are immersed. When these have been thoroughly imbued with the fluid, the trowsers are spread out one over the other on the canvas of the stretcher, the forks of the combined trowsers being made to lie a few inches away from and above the division in the canvas, and a many-tailed bandage placed, ready to be tied, under each leg. The material which is to form the abdominal binder is spread, with a many-tailed

[1] Read in the Military and Naval Section of the International Medical Congress held at Washington. Dr. Marston, in the absence of the author, read the above paper, enlarged upon the method of application, and expressed his opinion that it was an eminently practical and original suggestion. A short debate followed, in which several American surgeons took part and made some practical and pertinent observations.

Digitized by Google

bandage underlying it, transversely under the waist of the trowsers; and over all a thick layer of wadding is laid. On to the splint thus formed the patient is lowered in such a position that the margin of the fork of the trowsers corresponds to a point two inches and a half above the arms, and that his legs, being immediately over each leg of the trowsers, are about six inches apart at the knees. The fractured limb is held in good position by the surgeon, while two assistants, by tying together the tails of the bandage, bring the splint into close apposition with the posterior surface of the patient's legs, buttocks, and loins, and make the binder encircle the hips and abdomen. As soon as the plaster has set, the poles are passed through the folds in the canvas and the patient is removed. The whole dressing, not including the treatment of the wound and the setting of the plaster, can be applied in less than a quarter of an hour by a surgeon and two skilled orderlies. During the subsequent treatment of the case the canvas of the stretcher is never removed from underneath the patient. When an action of his bowels is about to occur, the poles are put in position, the halves of the canvas are separated, the patient is raised, and a bed-pan passed underneath him. He is lifted in a similar way when his wound requires to be dressed. The situation of this may require that windows be made in the splint and canvas: and in cases where it is apparent that this will have to be done, hoop-iron, if obtainable, should be placed between the trowsers, when first put in position, so as to strengthen the splint under the injured limb.

I regret that (unforeseen circumstances preventing my being present at the Congress) I am unable to show by demonstration how rapidly this splint can be applied and what excellent support it affords. I have not brought it to notice without having first thoroughly tested it by having had it tried on myself in person, and I would strongly urge anyone who may think of using it to do the same. Whoever does so will, I believe, be led to agree in this that, wherever reliable plaster-of-Paris can be obtained, this method of applying it will give very great help in the treatment of a class of wounds than which no others baffle more the skill of military surgeons. Of course the liability of plaster-of-Paris to deteriorate is a great drawback to its use on active service, and it should therefore be tested immediately before being employed. There are also, I know, other objections to its use as a material for splints, but these have force chiefly when it is used so as to surround a limb, and not when it is made to lie against one and take its shape. So employed, it is in my opinion the dressing most available for gunshot fracture of the lower limbs in connexion with transportation.

ON FROTHLESS ALBUMEN IN CERTAIN CASES OF ALBUMINURIA.

BY ROBERT KIRK, M.D. ED., F.F.P.S. GLASG.

IT is not a little remarkable that so striking a phenomenon as the frothing of albumen should have received no attention either from physiologists or clinical observers. The property on which it depends must be intimately connected with the purposes which proteid substances are destined to subserve in the animal system, and it varies in the degree in which it is manifested by different specimens of albumen. In the *Glasgow Medical Journal* for October, 1881, I pointed out the fact that in a few cases of albuminuria the albumen has altogether lost the frothing power, while in a much larger number of cases this property, although not entirely lost, is very much diminished in comparison with that of blood serum. The object of the present communication is again to call attention to these cases, but more especially to record a curious fact which I ascertained last winter—namely, that the more or less frothless forms of albumen appear to consist of a certain combination of serum-albumen and paraglobulin, and that when the latter is precipitated by dialysis or by saturation with salt the power of frothing is again perfectly restored to the albumen.

I first observed this with a watery extract of ox heart, which I had prepared for quite a different purpose. The solution was red, apparently containing a considerable amount of hæmoglobin, and I found on blowing a current of air through it that it was as frothless as water, not a single bubble rising to the surface. Some of it was thrown on a dialyser, and after twenty-four or more hours' dialysis I found, to my great surprise (for the experiment was tried accidentally so to speak), that it now frothed as perfectly as any specimen of serum albumen I had ever seen. There was a large precipitate of paraglobulin, and the mixture had become very viscid and proved difficult to filter. I at once tried the same experiment with a specimen of ropy albumen from an ovarian cyst and with a comparatively frothless albumen from a case of albuminuria, and in both with an identical result. It was even more decided when the paraglobulin was thrown down by neutralising the urine, saturating with magnesium sulphate, and keeping it for twelve hours or longer in a hot-air chamber at a temperature of 100°F. Indeed, merely stirring in a handful of salt was sufficient to produce an immediate and marked effect.

The explanation of this fact is not apparent. In my earlier experiments I had found that the paraglobulin of blood serum frothed nearly quite as well as the albumen, and the serum itself, containing both together, is, as every one knows, highly frothy. I had ascertained also that neither acid nor alkali had any considerable effect on the frothing power, and that neither saturation with salt, nor the removal of salt by dialysis, could destroy it when present. I had not, however, as now, tried the latter two procedures on the frothless forms of albumen, not having the slightest reason to suppose they would exercise any effect on them.

Albumen as it occurs in various exudations has often much less power of frothing than blood serum. I have seen a case of hydrocele serum (second tapping) in which the albumen was as frothless as water. In albuminuria, as far as my observations have gone, I have found that the frothless forms occur in acute nephritis, and generally in the absence of confirmed and chronic renal disease. In any case of albuminuria I invariably regard a deficiency of the frothing power as in itself a very favourable symptom—an opinion which I was led to express in 1881 in the paper above referred to. A case is there mentioned of a patient seventy-five years of age who recovered from severe albuminuria with uræmic symptoms, and enjoyed good health for several years afterwards, and whose urine throughout was nearly frothless. At present I have under treatment a woman of fifty-five years of age who is recovering from dropsy and albuminuria of three months' duration, and complicated with pleurisy, whose urine also, though highly albuminous, has always been less frothy than serum albumen. The experiment of precipitating the paraglobulin has been frequently tried in her case, and has never failed to restore the frothing in a wonderful manner.

To form an idea of the frothing of the urine, it is not sufficient merely to shake it up in a bottle. I have sometimes employed a U-shaped tube, through which air is drawn by an aspirator; but this is too troublesome for ordinary use. It answers tolerably well to put an ounce or two of the urine into a cylindrical jar fifteen or eighteen inches high and about two or three inches in diameter, and to blow a current of air through it by means of a long glass tube conveniently bent. A hand-bellows may be used, but the expired breath answers well, a full expiration giving a tolerably uniform quantity of air in each experiment. In this manner the difference between water, normal urine, various specimens of albuminous urine, and blood serum may be readily demonstrated.

Partick, Glasgow.

ON A NEW METHOD OF TREATING THE VOMITING OF PREGNANCY.

BY WILLIAM DUNCAN, M.D., F.R.C.S.,
ASSISTANT OBSTETRIC PHYSICIAN TO THE MIDDLESEX HOSPITAL.

THE complete and rapid relief which followed the local application of cocaine in the three cases here briefly recorded seems worthy of note:—

CASE 1.—Mrs. W——, aged nineteen (hospital patient), applied on March 11th, saying she "had not been able to keep anything down for the last month." The patient looked emaciated and ill; she was just two months pregnant with her first child. On examination, the uterus was found to be *markedly anteflexed*, and decidedly tender when pressure was made on the cervix. Sims' speculum was introduced, and the whole of the vaginal roof and cervix

Digitized by Google

freely painted with a 15 per cent. solution of cocaine, a probe covered with cotton-wool and soaked in the solution being carefully inserted into the cervical canal to the depth of three-fourths of an inch. A dose of peppermint-water was ordered (as a placebo) three times a day. The patient returned on March 18th, saying that *she had not vomited once since taking the medicine.* She has continued perfectly well since.

CASE 2.—Mrs. T——, aged twenty-six, nearly three months advanced in her second pregnancy, consulted me for severe vomiting, which had existed for a month. On vaginal examination the uterus was found to be normal in position, but tender on pressure. The same local treatment was adopted as in Case 1. No medicine was prescribed. The result of the treatment was precisely similar, for the patient did not once vomit after the application.

CASE 3.—Mrs. G. R——, aged twenty-three (a hospital patient), two months and a half pregnant, applied on June 17th for relief from constant vomiting, from which she said she had suffered for six weeks. On examination, the uterus was found to be somewhat anteflexed. The same treatment as the foregoing was adopted, except that no application was made to the interior of the cervical canal. Peppermint-water was taken three times a day. On June 24th the patient stated that she had had no vomiting for four days after her last visit, but that then it recurred, although in a less severe form. Another application of cocaine was made; but this time the interior of the cervical canal to the depth of three-fourths of an inch was painted. On July 1st the patient said that no further vomiting had occurred. She could take her food with a relish, and was feeling quite well.

Remarks.—If these cases be not mere coincidences, we have in cocaine, locally applied, a most valuable remedy for the speedy cure of that distressing condition—the vomiting of pregnancy. It will, however, be necessary, before we are in a position to form a definite opinion as to its efficacy, to apply it in many more cases, and it is in the hope that all who have an opportunity will try this simple remedy and publish the result that I venture to report the above cases. It seemed to me that the *modus operandi* of the cocaine would be to remove the morbidly hyperæsthetic condition of that portion of the uterus about the internal os which is supposed to exist in these cases. It is most interesting to note that in Case 1, where marked anteflexion was present, the vomiting completely stopped without any interference with the flexion. It is evident from Case 3 that in order to obtain the full effect of the cocaine it must be applied to the cervical canal, and herein lies the danger, for a careless or unskilful application might easily produce what is of the utmost importance to avoid—viz., abortion; still, with proper care there is very little risk, as I have many times made applications to the cervical canal during gestation without terminating the pregnancy in a single instance.

Harley-street, W.

CASE OF TRIPLETS, WITH MONSTROSITY.

BY H. J. CLEMENTS, L.R.C.P. & S., L.S.A., &c.

ABOUT Sept. 14th, while doing locum-tenens duty for Dr. Beeby, partner of Dr. Ilott of Bromley, Kent, Mrs. G—— called at the surgery to engage the services of Dr. Ilott, for her approaching confinement, which, as far as she knew, would take place about the middle of October. I saw her on this occasion, and inquired when she last menstruated. Her answer was she had not seen anything since her last confinement, which took place about the middle of January, 1886, and that she became pregnant during the time of suckling, but fixed on the middle of October as the most probable date for her confinement. I took particular notice of her appearance, which was very much drawn, with hollow cheeks and expression indicative of anxiety and pain. She informed me that for some time past she had experienced a grinding pain, and could not lie on her right side, and had sensations quite different from any she had ever felt before.

On Sept. 21st her husband called for Dr. Ilott to come immediately, as his wife was in labour pains. Dr. Ilott, being unable to go himself then, asked me to go for him. I arrived at the house at 6.45 P.M., and found Mrs. G —— in bed in a comatose condition, with little or no uterine action. I was told the liquor amnii had escaped at 3 A.M., but the pains were very slight and wearying all day. On examination, I found the os fully dilated, with the head presenting. I gave her one drachm of a solution of ergot and ammonia in a little water. Some short time after, uterine action showed signs of becoming a little more brisk, but soon died away again. I then discovered the head lower down in the vagina, with the left side of the face presenting, and, having a forceps with me, I introduced the upper blade only, and by its means as a lever brought the head into the proper position, but on taking away the blade it soon turned back again. The mother was growing weaker and uterine action was almost *nil*, so I put both blades of the forceps on, proceeding as before, with the upper one first, and delivered the head. I then withdrew the forceps, waited awhile for uterine help, but in vain, and with the left hand on the abdomen and the fingers of the right hooked round the neck of the child I simultaneously used pressure and traction with but very little result. I again waited awhile, but the uterus did not seem disposed to act, and feeling the delay dangerous to the life of the child, I introduced my finger and with some little trouble brought down the right arm. I repeated this with the left, and having both arms down, I hooked the fingers of my right hand into each axilla and made good traction, at the same time using pressure with my left over the abdomen. By exerting myself thus to no inconsiderable amount, I succeeded after a little time in bringing the child down below the ribs, but could not yet see the cord. Here there was a block. All along there was little or no hæmorrhage, the pulse was weak, and the mother expressed great sense of weariness and dread. I had by this time of course come to the conclusion that there was something abnormal present, and the first idea that suggested itself to me was that there was an unusually short cord attached to a strongly adherent placenta. I now became anxious for help in order to well manipulate the abdomen, and at the same time use traction on that part already exposed, as I believed this to be the only means now left for the expulsion of what remained. My wishes were soon gratified, for Dr. Ilott entered the house and came immediately to my assistance. He took the body of the child in both his hands and made traction backwards and forwards, while I, at the same time, used strong pressure and well kneaded the abdomen. This soon proved successful, for the left buttock appeared inclined to come, which it did, and in about a minute afterwards a broad surface joined to something else made its appearance; this turned out to be the back of another child, and without much more trouble was removed with the remainder of the body, and thus left in our hands an extraordinary specimen of a freak of nature. Nor was this at an end, for having tied the cords and wrapped up the prodigy in a flannel petticoat, I examined the vagina for the placenta, when, to my astonishment, I distinctly felt another bag of membranes unruptured, and feeling through it I found some toes or fingers easily distinguishable, as well as a soft mass, which clearly seemed to me to be the breech of another fœtus. Dr. Ilott then made an examination, and corroborated my opinion, and, there being total absence of pain, the membranes were ruptured, the liquor amnii escaped freely, and we proceeded as before—viz., with external abdominal pressure,—following the uterus well down until the fœtus was expelled by a breech presentation, and a living female child was in our hands. I again made an examination, and found the placenta quite low down, which, with slight external pressure, I easily removed with very little hæmorrhage. The uterus was found to contract very soon after, as was evidenced by its well-known feeling through the external abdominal walls resembling that of a cricket-ball. The mother was weak, but gaining strength, and experienced great relief at having got rid of her burden, though of course terribly grieved on learning the condition of her offspring.

I saw them twice a day up to Sept. 24th, and afterwards took the prodigies to the studio of a photographer, where I had them photographed in three different positions, which clearly shows the point of union, as well as the spina bifida. The grandmother, who nursed them, informed me that they could not retain the milk given them, so I tried to give them some myself in a teaspoon, and found them deficient in the power of deglutition, though I felt satisfied that it was not altogether wanting. They could not, however, take sufficient to sustain life; atrophy set in, and they died on the 24th at 8 P.M., having lived three days.

Description of monstrosity.—The weight a few hours after birth, accurately weighed by myself, I found to be

Digitized by Google

6 lb. 13 oz. Above and below the union they were like two ordinary children, with one exception—that the skin was somewhat wrinkled and had an unhealthy colour. The union commenced at the lower end of the lumbar vertebra, and extended to the end of the sacrum, but not exactly in the middle line of both, which would make them appear as back to back. The sacrum of one was united by the middle line to the side of the sacrum of the other, so that viewing them from behind they had but two buttocks between them. The sex was female, and it had externally the appearance of only one vagina being present. On examination after death there was found to be a double one, but no urethral orifice could be discovered in the usual site. The mons veneris and labiæ were abnormally large and swollen. There was but one anus, through which meconium passed freely. A spina bifida about the size of a small orange could be seen at the lower end of the lumbar vertebra, where the union of both commenced. There was no deformity anywhere else, as the features, bodies, arms, and legs were not wanting in any particular.

The other child still lives, and is right in every respect. I weighed it at the same time as the others, soon after birth, when I found it to be exactly 4 lb. There was but one placenta, which weighed 2 lb. 9 oz., and was divided into two compartments, one for the prodigy and the other for the separate child. That for the prodigy had one ordinary sized cord, with a supplementary one about half the size attached to its base as it entered the substance of the placenta. The other was covered all over with membrane, the substance of the placenta being nowhere exposed. The cord here went through the membrane, and was attached to the placenta at the wall of the compartment. I took it entire to the museum of the College of Surgeons, and found that there was no specimen like it there. The prodigy was also taken there soon after death, when it was found that, though they had not a specimen exactly like it in preservation, a cast of one similar to it was discovered on the shelves.

Family history.—The father was about thirty, strong, healthy, and born of healthy parents; one of his grandmothers died recently at the advanced age of one hundred and eight years. The mother, aged thirty, had four previous confinements, and suffered from puerperal convulsions with the first child. The third child is affected with infantile paralysis; the others are well. She had nine brothers and three sisters. Four of the brothers are dead; the sisters are all alive. One of the surviving brothers has always been deficient in mental power; one of the sisters is insane, and in a lunatic asylum. Her father and mother contracted a consanguineous marriage, being first cousins, children of two sisters. The mother relates that some three or fourth months ago she received a very great shock when going through the streets. Two men in a dog-cart, driving furiously along, got one of the wheels of their cart locked in a wheel of another cart standing in the street, and dragged it along for some distance. The suddenness of the incident affected her so severely that she was obliged to rest in a shop close by. She felt extremely faint, and soon returned home, but the incident made a deep impression on her.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ALARMING SYNCOPE FROM SYRINGING THE EAR.

By J. MIDDLEMASS HUNT, M.B.,
SURGEON TO THE THROAT AND EAR DEPARTMENT, NEWSHAM DISPENSARY, LIVERPOOL.

ON August 7th I was called to see E. G——, a boy of three years of age, and found him in a state of profound coma, with slow irregular respiration, rapid pulse, lividity of lips, cold extremities, dilated pupils—to all appearance, in fact, on the point of death.

The history I got was that the child had suffered from measles two months before, and since then had had a purulent discharge from the right ear. This was being treated, under the direction of a surgeon, by injections of a solution of boracic acid, and on the day in question, just as the mother finished syringing the ear, the child fainted. Till this happened he had been running about, and was apparently quite well. The mother first made efforts herself to revive the child, carrying him into the open air, but as his condition became worse I was sent for, and, arriving half-an-hour after the syncope began, found him as already described. The parents had not observed any convulsion, nor had the child at any time previously suffered from convulsions. After watching him for five or ten minutes, during which time his condition remained unchanged, I ordered mustard to be applied to the nape of the neck and the lips to be moistened with brandy-and-water. Giving the worst prognosis, I left, promising to return within two hours. When I returned I was surprised to find the child conscious and to all appearance well, except that he was somewhat pale and languid. I was told that a few minutes after the mustard was applied consciousness returned. Examination of the ear showed extensive destruction of the membrana tympani, but there were no signs of caries. The urine was free from albumen, and the child has remained well since.

Remarks.—I find a somewhat similar case recorded by Roosa in the *Archives for Otology* (vol. ix., p. 17), where a man, aged forty-five, passed into a state of coma after his ear had been syringed to cleanse it from a chronic purulent discharge. In Roosa's case the coma was equally profound, but does not appear to have lasted beyond a few minutes, though the patient was unable to leave the consulting room for two hours afterwards. Roosa does not offer any explanation of his case, in which no examination of the tympanic membrane was made. Probably such cases are due to a nervous reflex starting either from the terminations of the auditory nerve in the semicircular canals and labyrinth or from the tympanic plexus. I am inclined to the latter view, as to the course of the reflex, on account of the connexion, demonstrated by Lockhart Clarke, between the roots of the fifth cerebral, the glosso-pharnygeal, and the vagus.

THE ETIOLOGY OF SKIN DISEASES.

By F. AUGUSTUS COX, M.B. LOND.,
SURGEON TO THE WESTERN DISPENSARY FOR SKIN DISEASES.

I HAVE read with interest Dr. Frederick Pearse's note on the above subject. To label a particular eruption as "eczema," and, without regard to its causation or manner of development, regard and treat it as a definite pathological entity is, of course, not satisfactory. As regards "eczema," a good many causes have been assigned for it, yet it is not always possible to trace any particular case back to its origin—at any rate, if we exclude those cases caused by external irritants. The nomenclature of skin diseases is to blame for a good deal of the confusion that exists. For example, the term "eczema" itself is a most indefinite and misleading expression. Under it have been included the most varied lesions ranging from a simple erythema to the formation of pustules or scabs. If we could get rid of such a term as eczema, or never employ it without qualification, some progress would have been achieved, and we might hope to be more successful in our attempts to determine in any given case the cause which has been operative.

In the case of acne, several of the assigned causes are often simultaneously present, but it is not always easy to say which is the active one. Great stress has been laid on sexual irritation as a cause, but many authorities deny its influence. A medical man who had seen many cases once remarked to me that he had never seen but one in a married person, and that was in a man living apart from his wife. I cannot, however, corroborate this observation, having many times seen married persons suffering from acne, and one of the worst cases I ever saw was in a young married woman. I had recently under my care a young lady affected with tinea versicolor over the chest. Ordinary antiparasitic remedies were prescribed, and the affection quickly disappeared, but as it did so a well-marked patch of acne punctata took its place. I should, however, hesitate to suggest any causal relation between the two disorders. I should add that the acne punctata soon vanished on using a weak sulphur ointment, combined with a free use of soap and water.

In regard to one cutaneous disorder—psoriasis—mentioned by Dr. Pearse, our knowledge of its etiology is almost *nil*. Excluding heredity, to which it can often be traced, we can often discover nothing. It frequently seems by choice to

Digitized by Google

attack the most healthy people. As I once heard Mr. Malcolm Morris epigrammatically express it, "It is a disease of health." Most practitioners would admit the truth of this so far as the general health of the patient is concerned. Yet the lesions in psoriasis are well marked and their morbid anatomy accurately known. There is presumably a cause if we could only unravel the tangled web leading to it.

South-street, Park-lane.

CASE OF PUERPERAL PERITONITIS.

By FRANK STURGES, L.R.C.P. LOND., &c.

THE following case seems to present points of sufficient interest to warrant my wish to obtrude it upon the notice of the readers of THE LANCET. I will first give very briefly my daily notes.

Mrs. G——, aged thirty, multipara, a pale and delicate-looking woman, was delivered of a living child on Aug. 22nd at 7 P.M., after a labour that would have been quite normal but for a somewhat prolonged first stage (about ten hours). The placenta was expressed without any difficulty a little later.—Aug. 24th: Slept little, and complains of great abdominal pain. Light tapping with fingers reveals extreme tenderness over hypogastric and both iliac regions. Temperature 99·4°; pulse 80. Has vomited, and feels sick. Ordered milk and lime-water diet, half a grain of opium every four hours, and mustard and linseed poultices continually.—25th: Vomited and retched a good deal since last note. Lochia small in quantity, but very offensive. Peritonitis most acute over the whole abdomen. Temperature 100·6°; pulse 100, feeble. The uterine cavity was washed out with water coloured by iodine tincture. Ordered half a grain of opium every three hours; poultices to be continued; a diet of milk and lime-water, and a little strong beef-tea; and a dessertspoonful of brandy every four hours.—26th: Passed a better night. Has not vomited, and says she is much better. Light palpation still causes pain, but not so severe. Lochia more in quantity and less offensive. Temperature 99·2°; pulse 80, of better volume. Uterus again washed out, and treatment continued.—27th: Had a good night, and is much better. Lochia quite sweet. Light palpation causes little or no pain. Temperature 98·4°; pulse 64, and of fair volume. Diet to be milk and beef-tea; brandy omitted, and half a grain of opium given every six hours. Uterus again washed out. From this period nothing of note occurred, the convalescence being rapid and complete.

Now, this case is most interesting to me, probably largely on account of its gratifying termination. I have always regarded acute peritonitis coming on so soon (about thirty hours) after the commencement of the puerperal period as almost necessarily fatal, and on Aug. 25th the patient was so very ill that I hardly thought she could recover. With regard to the causation, there is much of interest. The woman was living as caretaker in an empty house, a house that had not been properly inhabited for some considerable time. In this house were three waterclosets—one, scarcely ever used, on the same floor as the room in which the patient was confined. And I believe that, although I was informed there was plenty of water and I never detected any drainage smell, the flushing of this closet had been much neglected. This, then, would be a sufficient cause, only there is something else to be told. The nurse who was present at the birth was suffering from an attack of acute tonsillitis, which rendered her barely able to discharge her duties; and when she showed me her throat I was greatly exercised in my mind as to whether I ought not to send her home, and whether, if she stayed, she could convey by any possibility septic poison to my patient. However, she stayed till Aug. 24th, when I was informed, on paying my morning visit, she had gone home, feeling too ill to attend to her work. Thus, for two nights the nurse had slept with the lying-in woman, and some time during the second night the peritonitis came on. And, I might add, the nurse went away, and the patient got better: was it because the cause was removed? And then, lastly, concerning the treatment. I have already told how I treated the case; but the nurse treated it also, and in this way. On the morning of Aug. 24th, before going home she gave the patient, without any authority, six much advertised patent pills. I did not hear of this till the following day, when I was told that Mrs. G—— had had two actions of the bowels causing such intense pain that she twice fainted. Mr. Lawson Tait has, I believe, advocated the treatment of these cases by Epsom salts; and although it would seem to me to require all Mr. Tait's great reputation to put that treatment into practice, I would not take upon myself to say that these pills administered by the nurse had not something to do with the recovery. For they were given early on the 24th; they acted twice in the night; on the morning of the 25th the patient was much worse, but during the day she changed for the better. We must also bear in mind, however, that on the morning of the 25th I injected the uterus with a solution of iodine, and by that time, too, notwithstanding aperient pills, the opium and counter-irritation were beginning to have effect. Should it be my misfortune to have another case of the kind, I shall certainly treat it with iodine irrigation, opium, and counter-irritation, and not with the aforesaid pills or Epsom salts. Still, I have considered it right to record this case in its entirety because of its peculiar and speculative interest, and because of the terribly fatal nature of the disease; and I ask members of the profession to take all the facts into their careful consideration and draw their own conclusions.

Beckenham.

VERY RARE PRESENTATION IN MIDWIFERY.

By W. H. BORHAM, L.R.C.P.E., M.R.C.S., L.M.

ON Sept. 20th, 1887, Mrs. C——, aged thirty-two years, was being attended in her confinement with her sixth child by a midwife. She had been in labour for two days, and the midwife left her for about an hour. On her return she found a loop of the funis, three inches in length, protruding from the vagina, and "something wrong above" in connexion with the head of the child.

The midwife sought for my attendance. Upon examination I found the cord hanging external to the vulva in a loop about the length stated; there was a slight pulsation in it, and it was getting cold. Upon introducing my fingers, I found the palm of the child's left hand was flat and pronated on the side of the child's occiput between it and the mother's sacrum. In the interim of the pains, which were flagging, I at once introduced my hand into the vagina, pushed up the child's hand and head, then gradually insinuated my right hand into the uterus and grasped the left foot, turned the child, and in a few minutes delivered the mother of a female child. It had suspended respiration, but the heart was still pulsating. With the usual treatment of warm bath, &c., the child was restored, and both are now quite well.

During a forty years' experience, and after attending some thousands of cases, I have never met with a similar presentation, nor do I remember reading of such a one by any authority. The fact of the hand resting on the head and the cord lying along the side of the wrist and thumb prevented that pressure upon the cord which would otherwise certainly have cut off the circulation of the blood and killed the child. Speedy version and delivery were necessary to save the child. All the parts of the female pelvis were capacious, and the soft structures amply relaxed. Some authorities state that both feet should be grasped and drawn down together in this operation, but most experienced accoucheurs in this operation, I think, will agree with me when I say that this is more easily said than done. To grasp both feet, which may be widely apart, with a cramped hand in the uterus, where the liquor amnii has escaped, is no easy task to accomplish, especially when one has so little time to secure a living child. It is better to be sure and bring the first grasped foot down, especially in such a case as the above, and I have never had any difficulty in easily delivering in this way. The joints and tissues in the new-born infant are so supple and flexible that no danger need be apprehended if carefully manipulated.

The mother of this child, when she was five months pregnant, fell downstairs, which may have altered the position of the fœtus in utero, and caused this unusual presentation.

UNIVERSITY COLLEGE HOSPITAL.

EPITHELIOMA OF TONGUE AND GLANDS; REMOVAL BY KOCHER'S METHOD; PATIENT FED FOR A FORTNIGHT THROUGH A TUBE RETAINED IN THE WOUND; COMPLETE RECOVERY.

(Under the care of Mr. A. E. BARKER.)

THE point to which we would direct special attention in this case is the method employed of feeding the patient after operation. Great advantage was derived from the use of the tube, the patient being well fed, and that without discomfort to himself; whilst, as Mr. Barker points out, no irritation or unnecessary disturbance of the wound was required.

S. W——, aged fifty-eight, was admitted on Aug. 20th, 1886, suffering from extensive epithelioma of the right side of the tongue and of the submaxillary lymphatic glands on the same side. The disease had appeared on the right side of the tongue about five months before admission, and had rapidly extended to the pillar of the fauces. When first seen there were enlarged glands beneath the chin and over the carotid vessels below the angle of the jaw. The suffering was very great and the difficulty of taking food extreme. The patient had come over from America to obtain relief.

In view of the extent of the disease, and the implication of the glands, Kocher's method of operating was selected as giving freer access to the latter and control over the lingual artery before section of the tongue; it also offered an opportunity of putting in practice a means of feeding the patient subsequently during the healing of the wound, which it had occurred to Mr. Barker might possess many advantages.

The mouth having been constantly cleansed with chlorate of potash lotion from the day of admission to the 25th, the face and neck were shaved and thoroughly washed with carbolic lotion. An incision was then made from a point just below the lobe of the right ear to the body of the hyoid bone, then horizontally forwards along the body of the latter for three-quarters of an inch, and then up to the symphysis of the jaw. The flap of skin thus marked out was now dissected up towards the jaw and the whole submaxillary space exposed. This was then completely cleared out of all glandular structures, an infiltrated mass being also removed from over the carotid vessels, and also from beneath the chin. In this dissection the facial artery and vein were divided and doubly ligatured. When the digastric space had been completely cleared of all secondary infiltration of glands the lingual artery was ligatured behind the hyoglossus muscle. Then Kocher's method was so far modified that the tongue was attacked from within the mouth. The latter being held open with a gag, the organ was secured with a cord passed through its tip and held over to the left. It was then detached from the jaw all round by means of scissors, which were made to cut straight down to the hyoid bone at once. When well isolated, it was divided with scissors obliquely across at its root from left to right, the left lingual artery being at once caught up with Wells' forceps. During this part of the operation but little blood was lost and no trouble was experienced. The first wound in the neck, provisionally closed with a carbolised sponge, was now open to the mouth and pharynx, and there was thus free access to the whole area of operation. This was then carefully cleaned, dried, and dusted with iodoform, and the two ends of the incision were stitched, the middle being left unclosed for drainage. Through this part of the wound a piece of rubber tubing about a third of an inch in thickness and eighteen inches long was introduced and passed well down the œsophagus, the other end being secured to the right ear. The neck around the edges of the wound was now dusted with iodoform and carefully padded with salicylic wool, a great mass of ordinary wool being packed over all round the neck to secure the head from movement, which end was fully attained when the mass of wool was firmly bandaged. The rubber feeding tube projected above the wool at the ear.

The patient suffered but little shock from the operation. In the evening a quantity of beef-tea was poured into the stomach through the rubber tube, without disturbing the patient or the wound in the smallest degree. This method of feeding was continued every four hours or so for sixteen days, and was a great improvement on the ordinary methods. The dressing was left undisturbed for two days, and was then replaced by fresh packing as before, the skin wound healing by first intention, except at the spot where the tube lay. The latter was left *in situ* until the floor of the mouth was nearly healed, and was only removed on Sept. 9th. Cicatrisation was rapid and unaccompanied by any trouble; the temperature remained normal throughout, and the patient was very cheerful and rapidly regained strength from the regular feeding. The latter was carried out in the simplest manner by introducing the point of a funnel into the tube lying outside the dressings, and through this pouring in beef-tea, milk, eggs, &c. The patient had not to move, and the mouth was left undisturbed.

Remarks.—The chief points of interest in this case are, first, the extent of the operation. Not only was the tongue removed with the structures of the floor of the mouth on the right side, but all the glands of the submaxillary space from the chin to the lobe of the ear. And yet there was but little shock—a fact due probably to the ease with which bleeding can be arrested in operating from without. The next point to be observed is that by operating as above it was possible to keep the wound in the mouth absolutely clean from beginning to end, and at the same time to maintain the parts in a state of perfect rest. The patient had nothing to say to his own feeding; in fact, it could be done while he was in any position without disturbing him. No food passed through the mouth, consequently the wound in the latter could be treated like any other wound, and did not need even to be washed out receiving only a puff of iodoform from time to time. As there was no swallowing, there was no pain. Mr. Barker was much struck with the superiority of this method of feeding over that by enema or nasal tube, and has adopted it since in other similar cases with equally satisfactory results.

The patient was seen some months later, with no trace of recurrence, looking very well, and very much pleased with what had been done for him.

OLDHAM INFIRMARY.

CASE OF PSEUDO-HYPERTROPHIC MUSCULAR PARALYSIS IN ITS FIRST STAGE, OR PROGRESSIVE MULTIPLE NEURITIS; RECOVERY.

(Under the care of Mr. FAWSITT.)

FOR the following notes we are indebted to Mr. John J. Weaver, late house surgeon.

P. B——, aged twelve years, a rope-maker (i.e., engaged in making or repairing ropes), was admitted on Oct. 1st, 1886. About five weeks before admission he noticed some numbness or "cramp" in the thumbs and fingers of both hands, especially affecting him in the early morning, and he was in the habit of calling his mother up about 5 o'clock in the morning to rub his hands on account of the pain. The mother would rub them for about ten minutes or so at a time. She thought the pain had something to do with the boy putting his hands into water at his work. This affection of the fingers lasted on and off for about a fortnight, and was then followed by the pains in the calves of the legs described below. The mother noticed that about this time the boy seemed less inclined than usual to run about, but preferred to sit down and read to her instead. Three weeks before admission the patient noticed a "dull" pain in the calves of his legs, which came on about four times a day, and lasted about ten minutes at a time. Less than a week after this pain in the calves commenced, the boy fell one day while at work, and then found that he could not get up again. He crawled to a stake in the ground, and by means of that raised himself up. This fall was the first symptom that caused the mother to seek medical advice, and for which she brought the boy to the infirmary. About a week after the fall the patient stated that he had on one occasion some aching pain at the bottom of the back, lasting about

Digitized by Google

fifteen minutes; no recurrence since. For about three weeks before admission he was in the habit of wetting his bed now and then—not an old habit with him. It occurred also once or twice after admission during the first week or so, but ceased altogether afterwards. Previously to his present illness he has always had very good health, and been able to run about as well as other boys. Family history: Father and mother living and healthy; one sister, aged eighteen, healthy; one brother, aged sixteen, consumptive. Both sister and brother were seen at the infirmary. No history whatever of any previous similar case in the family. Mother's sister's children in Australia; none affected.

On admission the patient was a bright, intelligent, and healthy-looking boy. When put on all fours he was quite unable to get up. His efforts to get up were characteristically those of pseudo-hypertrophic paralysis. When asked to stoop and pick up a pin from the floor he raised himself with great difficulty from the stooping position by placing his left hand just above his left knee, and so pushing himself up. He could get up easily from the sitting position, as from a chair, to the standing position. Gait somewhat waddling. He raised his knees up rather higher than natural, and put his feet down again forcibly; easily tumbled over on turning round, or on the least push. He was quite unable to get up the stairs leading to the ward, and had to be carried. He could walk about the ward, but was easily tired. When standing the legs were held apart and were unsteady; there was slight rocking of the body backwards and forwards, and he seemed unable to stand perfectly still. Decided increase in lumbar curve, and abdomen protuberant. A plumb-line let fall from the most prominent dorsal spines easily escaped the sacrum. Calves of legs hard, the hardness being very noticeable even when the patient was lying on his face on the bed. Calf muscles apparently not enlarged, though they compared favourably in development with the rest of the muscular system. Measurement of calves (greatest diameter): right calf 10½ in., left calf 10⅝ in. No apparent enlargement in muscles of thigh or in the infra-spinati. General muscular system poorly developed. Pectoral muscles much wasted, especially the lower or sterno-costal portions. The latissimi dorsi muscles could not be brought into view. No wasting of muscles of hands or thumbs; no weakness of hands out of proportion to general muscular development. Muscles of face unaffected. Sensation everywhere unaffected. Intellect very good. Knee jerk in both legs absolutely lost. No ankle clonus.

Oct. 4th.—Electrical reactions: Patient flinches so much with even the weakest currents that it is very difficult to be sure of the results. The gluteal muscles give with the faradic current apparently diminished reaction; with the galvanic current the reaction seemed at first apparently increased, afterwards uncertain. The reactions of the calf muscles to both forms of electricity are greatly diminished.

5th.—Patient begins to walk better. Can now get up from the stooping position after picking something off the floor with difficulty, but without placing his hand upon his knee. He cannot get up from all-fours.

6th.—The boy can to-day for the first time get up from the all-fours position by placing his left hand upon his left knee.

7th.—Patient vomited yesterday, morning and afternoon, and also this morning. Constipated; ordered aperient. No recurrence of vomiting.

8th.—Patient can get up from the stooping position without the use of his hand upon his knee. In getting up from the all-fours position, still uses his left hand upon his left knee; walking much improved. He appears to feel both forms of electricity more on the left side of the body than the right.

10th.—Patient was allowed this afternoon to go out into the infirmary yard, but ran away to his home, which is only a few streets away from the infirmary. He was, however, brought back by his mother in the evening. He was a good deal distressed at being brought back, and his walking was much worse. He was quite unable to get up the stairs to this ward, but had to be assisted by someone supporting him on either side.

11th.—Dr. Ross, having kindly promised to see the case, the boy was taken over to Manchester. In getting into the cab or carriage, the step being rather high, he placed his left hand upon his left knee to push himself up. Dr. Ross pointed out the very extensive fibrillary contractions in the muscles of the back, legs, and triceps muscles of the arms; also the general muscular wasting. Grasp of hand, fair strength. Patient, sitting and resting heel upon ground, is able to raise toes from the floor. Dr. Ross apparently easily obtained electrical reactions in the muscles of the back by faradism (even with dry electrodes), but with galvanism the reactions could not be made out on account of the patient's flinching. This was the only occasion on which Dr. Ross saw the case, and, as will be seen from the notes, the boy's condition by this time had very much improved. From the symptoms as they then existed, Dr. Ross was therefore unable to confirm the diagnosis of pseudo-hypertrophic paralysis. One note, made at the time, but which until now on account of its uncertainty has been omitted, is to the effect that in grasping anything "the dorsum of the hand was drawn slightly towards the extensor surface of the forearm in the act, one hand (left?) more so than the other." On repeated trials it was very uncertain, and therefore it was afterwards omitted. It proves, however, that there was no loss of power of extension of the wrist.

* Date of admission. † Patient discharged.

It will be noticed that at first there is a gradual decrease in size of both calves, followed later by a gradual increase in size, accompanied then by a gradual increase in the patient's weight.

Treatment.—On the assumption that the case was one of pseudo-hypertrophic paralysis, the treatment adopted was that recommended by Duchenne for the first stage of the disease—viz., faradisation and shampooing. The boy was therefore shampooed daily for about twenty minutes at a time, the muscles being thoroughly well rubbed and squeezed, and electricity, sometimes one form, and sometimes the other, but most frequently the faradic current (being much better borne), was applied directly to the muscles. In addition, a mixture containing syrupus ferri phosph. comp., and five-minim doses of liq. strychniæ and liq. arsenicalis was prescribed. The boy was kept in bed as little as possible and encouraged to move about.

Jan. 7th, 1887.—The patient was discharged from the infirmary. With the exception of the total absence of knee jerk, he appeared to be in perfect health. His gait was natural; he could get up from all-fours naturally and without difficulty, and could again run about perfectly well. He was seen again on Jan. 17th.

Feb. 17th.—Patient was seen at the infirmary. The improvement is still maintained. The knee jerk is still absent. The patient's general muscular development is much improved, especially the condition of the pectoral muscles. The latissimi dorsi muscles also can now be made out. The calf muscles have still further increased in size, both calves now measuring 11½ in.

July 11th.—This was the last occasion on which Mr. Fawsitt saw the boy, six months after his discharge from the infirmary. The only trace of any disease that could then be found was the fact of the knee jerk being still absent. But on this occasion for the first time, though he had tried the method at all previous examinations, a very slight knee jerk was obtained by getting the patient at the same time to interlock his fingers and pull upon them (Jendrassik's method). The jerk was very slight on either side, but slightly more marked on the left side than on the right. The calves now measured 12 in. The boy got up from all-fours position with perfect ease.

In addition to the above account, one or two facts which cannot so well be put under dates may be added. First, as to the patient's manner of getting upstairs. On admission the boy could not get upstairs at all, not even with the help of the banisters. As his condition improved he was able to

Digitized by Google

get up by pulling himself up by both hands, the hand nearest the banister being placed on the top of the banister and the other on the banister rails. At the time of his discharge from the infirmary he was able to get upstairs without touching the banisters. The boy's intelligence was very good, as shown by his clear answers to questions, and by the fact that soon after his admission he proved himself the best draughts player in the ward.

Remarks by Mr. WEAVER.—I am fully aware of the difficulty of diagnosis in this interesting case. Undoubtedly at first sight the case appeared from the collection of symptoms and their well-marked nature to be a case of pseudo-hypertrophic paralysis, and as such I believe it was certainly regarded at that time by all who saw the boy. On different occasions soon after his admission to the infirmary this patient was seen by each member of the medical staff, and also by one or two occasional medical visitors to the infirmary, and although the absence of any marked enlargement of the calves or other muscles was noted, the diagnosis of pseudo-hypertrophic paralysis was on no occasion disputed. When, however, later, it was found that the boy's calves were not increasing in size, but rather decreasing, and that at the same time his general condition as to walking, getting up from the floor, &c., was rapidly improving, in my own mind at least a doubt arose as to the diagnosis. At this time, however, I was inclined, rightly or wrongly, to regard the decrease in size of the calves as possibly due to the smaller use of the muscles, resulting from the change of the boy's circumstances, involving the confinement in a hospital ward, and the additional necessity of the boy keeping his bed at times for the purpose of treatment by shampooing and electricity. I was also aware that almost every conceivable condition of the muscles as to size had been recorded in pseudo-hypertrophic paralysis, and that even, as Dr. Gowers states, "the absence of muscular enlargement is of little significance."[1]

The actual size of the calves of this patient is, I think, worthy of note, though I do not wish to lay much stress upon this point. In this boy of twelve years, in whom the general muscular system was poorly developed, as noted by myself and afterwards by Dr. Ross, the right and left calves measured respectively 10½ in. and 10⅝ in. From a few comparative measurements I have made of calves of other patients about the same age I believe this patient's calves to have been rather above the average size. They may be compared also with a case of pseudo-hypertrophic paralysis recorded by Dr. Gowers,[2] in which in a boy aged thirteen years and a half the calves measured respectively 10½ in. and 10⅝ in., and are thus described—"Their undue size and firmness were very distinct"; and a case recorded by Mr. W. Adams, in which in a boy aged fifteen the calves are described as "large and prominent, each 9½ in. in circumference."[3] But regarding the muscles as not markedly enlarged, the case still seemed to me to correspond exactly in all its symptoms with the first stage of pseudo-hypertrophic paralysis, in which, as described by Duchenne, there is loss of strength without muscular hypertrophy, a stage of the disease also recognised by Charcot as "the first clinical stage noticed by all observers, a period in which the only appreciable symptoms consist in a more or less marked weakness of certain muscles which do not as yet exhibit any apparent hypertrophy, and which even sometimes show themselves manifestly atrophied."[4] Lately I have been able to compare the case with two cases of recovery from pseudo-hypertrophic paralysis recorded by Duchenne in the *Archives Générales de Médecine*, 1868. As considerable doubt has been thrown by most authorities on the nature of these cases, I may be allowed to point out that the two cases of recovery were respectively the ninth and thirteenth cases of a series of thirteen cases of hypertrophic paralysis, upon which Duchenne founded an exhaustive and accurate description of the disease as it is known at the present time. The description was published in 1868. Duchenne had met with his first case of pseudo-hypertrophic paralysis in 1858; his first case of recovery (the ninth of the series) occurred in 1863; his second case of recovery (the last of the series) in 1867. Of the first of these two cases, that of a boy aged seven years and a half, though the details are not fully reported, Duchenne says: "When I was first called to this young patient I made out the whole of the symptoms characteristic of pseudo-hypertrophic paralysis, but the apparent hypertrophy is slight and limited to the gastrocnemii; the lordosis is moderate (the father says it has increased)."[5] The second case of recovery, the case of a girl aged six, is fully reported as having all the characteristic symptoms of pseudo-hypertrophic paralysis, including separation of the legs while standing and walking, throwing back of the body (lordosis), waddling gait, the characteristic method of getting up from all-fours by putting the hands on the knees and mounting up the thighs.[6] In this case also the size of the muscles of the lower limbs is reported as "far from attaining the ordinary proportions of a more advanced stage of the disease," but as "contrasting with the thinness of the upper extremities." The treatment of this case is given in detail further on in the articles (p. 578). The different phases of this last case were evidently followed up closely by Duchenne, as he himself states.[7] It seems therefore impossible, whatever may have been the nature of these cases, to have any doubt as to the symptoms. The close resemblance of these two cases and the case I have reported I think is clear.

After the patient had left the infirmary I submitted the notes of the case to Dr. Gowers, and he expressed the opinion that the case was "certainly one of the muscular disease of which pseudo-hypertrophic paralysis and idiopathic atrophy are varieties. To which of these varieties your case belongs is a question to which different authorities might give different answers..... I should myself place it with pseudo-hypertrophic paralysis. The condition of the latissimi and pectorales, so far as my experience goes, is a conclusive proof of the nature of the malady." To account for the rapid onset and rapid improvement, Dr. Gowers is of opinion that in this case there was "a supra-added functional impairment of the nervous system which was manifested most by the muscles that were weakest, and so produced the semblance of a more advanced stage of the disease."

Dr. Ross, on the other hand, regards the case, "with cases of the kind reported as occurring in children after measles, chorea, scarlet fever, rheumatism, diphtheria, and other diseases, as a case of progressive multiple neuritis." Dr. Ross also considers that the cases of chronic poliomyelitis occurring in infants, as described by Dr. Bennett, belong to the same group.

If this case is one of progressive multiple neuritis, is it not possible to go a step further, and regard pseudo-hypertrophic paralysis itself as a progressive multiple neuritis? May not the pathological change in the muscles in pseudo-hypertrophic paralysis be regarded as a special manifestation of the later stages of the disease, and dependent perhaps, as Duchenne, after discarding the spinal origin of the disease, held, on a lesion of the vaso-motor system?[8] The frequent occurrence of vaso-motor changes in multiple neuritis has been pointed out by Dr. Buzzard;[9] and that a change in the muscles corresponding anatomically with the changes observed in pseudo-hypertrophic paralysis may follow a nerve lesion is also made clear by a case recorded by Hitzig and quoted by Dr. Gowers, in which, after an "injury to the nerves of the arm near the shoulder-joint, a slow increase in the size of the arm resulted, and the condition of the muscles was found, by harpoon examination, to be the same as in pseudo-hypertrophic paralysis."[10]

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, Oct. 5th, W. F. Cleveland (Vice-President) in the chair.

A gracious acknowledgment of the address from the Society to the Queen, on the occasion of Her Majesty attaining the fiftieth year of her reign, was received from the Home Secretary.

Mr. BUTLER-SMYTHE showed a Fibro-cystic Tumour of the Uterus, together with the Uterus and Ovaries, which he had removed that afternoon.

Mr. ARBUTHNOT LANE read a paper entitled "What are the Chief Factors which determine the Differences which exist in the Form of the Male and Female Pelves?" The author criticised the supposition that many, if not all, of the differences which exist in the form of the male and female pelves are due to force exerted by the femora and sacrum upon the innominate bones. He considered that the conditions of the thorax and pelvis are exactly analogous in the two sexes, and described in detail the manner in which the female thorax differs as a whole and in its constituent parts from the male thorax. He thought that the factor which determines the altered form of the female thorax from the male thorax (which he regarded as the original type) is the additional function performed by the former—namely, that of accommodating the fœtus during the later months of pregnancy. In the case of the pelvis, that of the female performs one function in addition to those performed by the male pelvis. That additional function is the support and transmission of the fœtus, and he regarded this as the sole factor which determines the variations in form in the two sexes. He thought that there is a fallacy in arguing from the manner in which certain forces produce changes in the pelves of diseased female subjects during the lifetime of a single individual, that the same forces acting upon a healthy female subject determine this peculiarity in the form of the pelvis, and that, should these forces be absent, the characteristic peculiarities do not result. He attempted to prove this point by applying the same argument to the analogous condition of the female thorax. He discussed the two most common variations in the form of the male pelvis and their probable cause, and showed that these variations do not occur in the female subject. The pressure exerted by the fœtus, represented as a developmental factor, is the cause, he considered, which prevents the occurrence of such variations in the female subject. He then alluded to pressure changes due to carrying loads upon or in front of the trunk, and from premisses gathered from these several points came to the conclusion that the sole determining factor of the variations in the form of the male and female pelves is, as in the case of the thorax, the force or pressure exerted by the fœtus.—Dr. HERMAN agreed with Mr. Lane in holding that the form of the pelvis was due to inheritance—i.e., to influences acting on many generations of ancestors—more than to forces acting during the life of an individual. But he thought the way in which the shape of the pelvis was modified in transmission through many generations was mainly this—that women with well-shaped pelves were able to bear large strong children, likely to survive and to inherit and transmit that type of pelvis; while women with small pelves produced either stillborn children or small weak children, not so likely to survive, and so a stock with small pelves tended to become few. If Dr. Herman interpreted literally Mr. Lane's view of the way in which the shape of the pelvis was modified—viz., directly by the pressure of the head during labour—he could not agree with him. The head only pressed on the bones bounding the pelvic cavity during the second stage of labour. This stage on the average lasted less than two hours. Supposing the individual to have ten children (which was the largest estimate of the average), this made twenty hours' pressure during the whole of life, and usually no part of this pressure was exerted till after ossification was complete. He could not attribute any appreciable influence on the shape of the pelvis to pressure so brief and intermittent, exerted on hard, fully ossified bones.—Dr. PLAYFAIR said that Mr. Lane seemed to assume that pressure was generally described by authors on midwifery as determining the shape and dimensions of the female pelvis. He could recollect no modern text-book in which such a reason was given, the generally received explanation being that the increased size of the female pelvis was caused by the fact of the reproductive organs being contained within the pelvic cavity in women, and not external to it as in the male. It seemed very probable that a process of evolution might in time produce pelvic changes from constant factors, but not from accidental and occasional circumstances such as the presence of a fœtus in utero.—Dr. GALABIN had never understood that the mechanical effects of the body weight and muscular action were supposed to bring about the characters special to the female pelvis, but that the peculiarities of the female had been ascribed to the forces of development or the presence of the genital organs in the pelvis. If any peculiarity in an individual of one sex tended to be transmitted to the same sex more than another, he thought it might be capable of proof in the breeding of animals. Dr. Galabin thought that any special character, as size, colour, or strength, was transmitted to sons and daughters equally. The principle would be one of great interest as regards the future of our race if it were established. Strong-minded women were wont to ascribe any slight inferiority of woman's intellect which others might admit to the fact that women have been kept in a kind of slavery for many generations. He had always thought this was a fallacious argument, and that if women had in any way suffered, their sons would be the losers as well as their daughters. If Mr. Lane's principle were true, the case was altogether different; and if women exercised sufficiently their intellects and their bodily powers, they might in course of generations not only wipe out any slight mental inferiority, but come to equal or even surpass the men, both in average stature and muscular strength.—Dr. MATTHEWS DUNCAN had greatly admired Mr. Lane's former papers on the skeleton, and took special interest in the explanation of the changes of the pelvic joints at the end of pregnancy by mechanical influences.—Dr. CHAMPNEYS wished Mr. Lane to name any eminent obstetric writers who assigned sexual peculiarities to causes common to the sexes. He had never met with such a statement. The effect of pressure on respiration cannot begin before the sixth month, which leaves three months in each pregnancy, or thirty months in ten pregnancies, and against this we have to put the remainder of the whole of a lifetime of, say, sixty years. The production of alterations in the skeleton during pregnancy was one thing, and the alteration of the skeleton by laborious occupations was quite another thing.—Mr. LANE, in reply, was sorry that it would be impossible to attempt to answer offhand the many questions and criticisms, which would necessitate a complex and lengthy reply, but preferred to base his case on the material contained in the paper.

Dr. J. MATTHEWS DUNCAN then read a paper on Tonic Uterine Contraction without Completeness of Retraction, in which he called attention to the occurrence of a rigid, spastic condition of the uterus, especially just after delivery, without complete retraction and while the uterus has no contents opposing complete retraction or closing. In this state the hard uterus has a globose cavity. He more particularly called attention to the occurrence of hæmorrhage from the placental site while the uterus is in this state of firm spastic contraction with incomplete retraction, and mentioned cases. He regarded this hitherto unknown or unrecognised condition as probably affording an explanation of the well-known difference of opinion among obstetric authorities, some asserting the occasional occurrence of hæmorrhage after delivery from a hard contracted uterus, some denying it. A similar condition, he believed, occurs very rarely in the unimpregnated uterus.—Dr. HERMAN had published a case in THE LANCET, 1882, p. 1110, to illustrate the practice of injection of fluid into a vein. This was a case of secondary hæmorrhage coming on nine days after delivery. When seen by Dr. Herman the uterine cavity was globose and large enough to contain a fœtal head, and its walls were hard and rigid. The interior was swabbed with solution of perchloride of iron, and this was followed by thorough contraction of the uterus and arrest of hæmorrhage.—Dr. HORROCKS asked if the cervix as well as the fundus was affected by the tonic contraction, because, in regard to cavities such as the uterine and vesical, when the detrusor contracted the sphincter dilated. In Dr. Duncan's case, though the contraction of the uterus was tonic, it was incomplete, leaving an actual cavity. He mentioned a case in his own practice where bleeding came on ten days after labour. The fundus was contracted and hard, and yet the

Digitized by Google

cavity was not closed.—Dr. GALABIN was specially interested in hearing this paper, because he had thought that in a former paper Dr. Duncan had not distinguished a sufficient number of conditions in which the uterine wall might possibly be. He had understood him to identify that state of continuous action or tetany of the uterus with retraction. Dr. Galabin considered it was quite different, and more analogous to the post-partum condition now described. Retraction was a normal sequence of contraction. Continuous action was abnormal, and might be even antagonistic to retraction, for after such continuous action the uterus was liable to post-partum hæmorrhage. He remembered a case of cancer of the whole cervix, in which the uterus passed into a state of continuous action without any rhythmical pains having occurred, and the pulse became accelerated as in prolonged labour. Cæsarean section was performed. The uterus did not retract. Hæmorrhage took place from the placental site, and was only stopped by perchloride of iron. He thought such a condition might have a distinct analogy to rigor mortis. In rigor mortis a muscle was rigid as if strongly contracted, but if the tendons were divided the muscle did not retract in the least. The condition was really one of stiffening.—Dr. CLEVELAND said he had been sometimes puzzled to account for bleeding after natural labour where the uterus seemed of natural size and contracted, but as these cases occurred in delicate women he attributed them to the effects of a hæmorrhagic diathesis. He was convinced that in earlier experience his anxiety to remove clots from the uterus may have been carried too far. He now believed that where bleeding resulted from imperfect coagulation it was necessary for a clot of some size to remain within the uterus.—Dr. CHAMPNEYS thought that these cases threw some light on the vexed question of the action of ergot, which in some cases seemed to produce tetanus of the uterus without reducing its size or producing retraction.

Dr. JOHN PHILLIPS read a paper on a case of Pregnancy complicated by Secondary Hepatic Cancer. The patient, aged forty, mother of nine children, was operated upon in November, 1883, for scirrhus of the right mamma. Six months afterwards she was seen by the author for considerable pain in her right side; she was then six months pregnant. The pain increased in spite of all remedies, and her condition became so grave that after consultation induction of labour was performed. An easy labour followed, and, on the uterine tumour lessening, the liver was found enlarged and covered with umbilicated bosses, probably of a malignant nature. Jaundice and ascites appeared, and she died comatose three days after her confinement. The author made a few remarks as to the treatment in these cases, confining his attention more particularly to the rectitude of induction of premature labour. He also quoted one other case of a similar character.—Dr. HERMAN had read a paper before the Society[1] on the complication of pregnancy with cancer of the genital canal. In that paper he had discussed the influence of pregnancy on cancer of the genital organs, and had said that from the greatly increased blood supply to the breast and uterus during pregnancy we should expect that cancer of those parts would grow quicker if the patient became pregnant, and he had quoted a case which showed that this was so. A colleague had since communicated to him another case which showed the same thing. Dr. Phillips had referred to authors who were of opinion that pregnancy retarded or suspended the growth of mammary cancer. Dr. Herman believed this was an opinion not supported by observation. He had shown that in cancer of the uterus pregnancy frequently ended in the birth of a decomposed fœtus due to the cancerous cachexia causing the intra-uterine death of the child. This was a strong reason for bringing on labour prematurely as Dr. Phillips had done. Dr. Phillips had spoken of Cæsarean section being dangerous for the child. He doubtless based this opinion on the fact that the statistics of this operation showed a high infantile mortality. Dr. Herman thought statistics were here misleading. The risk which the child incurred in Cæsarean section was almost nothing, and the high death-rate of the children arose from such circumstances as too late performance of the operation, want of attention to the child at the time of operation, &c. If the operation were done when the child was alive, and with proper precautions for its safety, there was no reason why its life should be lost.—Dr. JOHN PHILLIPS, in reply, thought that induction of premature labour was preferable to Cæsarean section.

[1] Trans., vol. xx.

Dr. JOHN PHILLIPS also read a case of Hæmatocele successfully treated by Operation. A young married woman was attacked during menstruation with rheumatic symptoms. There was an aortic systolic murmur. Metrorrhagia continued for a month. A tumour the size of a Tangerine orange was found in Douglas's pouch, and after seven days a large swelling had formed in the left broad ligament, pushing up the uterus to the right, and producing a considerable abdominal swelling. The tumour descended towards the rectum, and in consequence of the precarious condition of the patient aspiration was performed, with no result. The next day the cyst was opened under ether per vaginam with a Pacquelin's cautery, and a large amount of blood clot let out. A Keith's ovarian drainage tube was inserted. The tumour rapidly subsided, and the patient made a good recovery.—Dr. GALABIN thought the case of interest as bearing upon the question when vaginal section and when abdominal section should be chosen if it became necessary to operate on a hæmatocele. He had never intentionally opened a hæmatocele, but had twice made an exploratory abdominal section with good result in cases which turned out to be hæmatocele, not dependent on extra-uterine fœtation. In both cases there was an elastic tumour reaching to the umbilicus. In both the peritoneal cavity was washed out with hot water, the contents of the hæmatocele having in one of them been in an intensely fetid condition. In one of these cases double pyosalpinx was found and removed, and the advantage of abdominal section was its allowing the removal of sources of mischief.—Dr. HERMAN thought that in cases in which the formation of hæmatocele was followed by gradually increasing pyrexia, the practice which he followed—viz., to let out the blood—was the right one. The majority of cases of hæmatocele got quite well under expectant treatment.—Dr. AMAND ROUTH thought Dr. Phillips' practice was the correct one. An incision into the tumour per vaginam was less dangerous than an abdominal section, and in the former the peritoneal cavity was not opened, as the bulging downwards of Douglas's pouch proved that adhesive peritonitis had closed this above.—Dr. CHAMPNEYS said that, where it was necessary to open a hæmatocele, it was certainly best to open it freely and drain and use antiseptic precautions. Much of the bad results in the past were, he thought, due to aspiration without free opening and drainage, septic matters being introduced into the sac without free escape.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

A GENERAL meeting of the Association was held at the rooms of the Medical Society on Thursday, October 6th. The chair was occupied by the President, W. S. Savory, Esq., F.R.S. The Council reported that Mr. Charles Paget's paper on School Sanatoria had been printed and distributed to members, further copies being obtainable from the publishers, Messrs. Churchill, at one shilling each. It was also stated that the Council intended to bring before a future meeting of the Association a code of suggestions as to the construction and maintenance of school infirmaries and sanatoria.

Dr. Hunter Barron, medical officer to Christ's College, Finchley, and Dr. R. P. Smith, medical officer to King Edward's School and assistant medical officer to Bethlehem, were elected members of the Association.

A discussion on "Some points in the Construction and Maintenance of School Sanatoria" was then opened by Dr. Shelly, medical officer of Haileybury, who deprecated the confusion arising from the common employment, as interchangeable and synonymous, of the terms "infirmary" (which should stand for the building in which ordinary non-infectious illness and accidents only were treated) and "sanatorium" (which, in default of a better substitute being invented, might be used to indicate the building reserved for the treatment of cases of infectious illness only). The desirability of providing sanatorium accommodation in all cases, the proportion which the accommodation for patients and nurses should bear to the size of each school, the provision to be made for treating school servants in sanatoria, and several other points connected with the construction and maintenance of such buildings, were brought before the meeting, and provoked a full discussion. Any members who have not received their copies of Dr. Paget's paper are requested to communicate with Dr. Alder Smith, Christ's Hospital.

CAMBRIDGE MEDICAL SOCIETY.

A MEETING of the above Society was held on the 8th of July, Mr. E. Carver, F.R.C.S., President, being in the chair.

Supernumerary Tooth.—Mr. CARVER exhibited a photograph of a child, aged six years and a half, showing a tooth growing from the right lower eyelid. Through the kindness of Mr. A. W. Stocks he was able to give the following history of the case. The patient, W. H——, was under the care of Mr. A. Young in the Salford Hospital, and "when born had a small excrescence on the lower lid of the right eye. This increased in size until he was about four years and a half old, when there appeared on the outer side a small white spot, which was found to be hard, and gradually the crown of a tooth (canine) was protuded until the whole tooth obtruded. In this condition it remained until removed. The fang of the tooth is somewhat bulbous. The number of deciduous teeth is perfect, and he has cut the upper and lower middle incisor teeth." Mr. Carver remarked that the number of milk teeth being perfect, this tooth could not be looked upon as a canine of the temporary set in an abnormal position, that its form and imperfect development pointed rather to its being a supernumerary tooth. That it was not uncommon to meet with these supernumeraries during the first and second dentition, particularly in the upper jaw, either within or without the dental arch more frequently in the latter situation—e.g., in the nasal fossa,—and occurring as they often do in the region of the incisors, some have looked upon their appearance as a return to the normal mammalian type of six incisors. He alluded to the small size of the superior maxilla in early life, and that with a full complement of milk teeth a supernumerary tooth might be developed at some distance from the dental arch; but the position of the tooth under consideration—i.e., in the lower eyelid—was not so easy of explanation. After these remarks, Mr. Carver invited Dr. Cunningham to favour the meeting with his views on this interesting case.—Dr. CUNNINGHAM said supernumerary teeth may be divided into two groups—those that may be ranked with one or another of the members of the dental series, and those which differ in form from the latter, called the conical teeth. Those belonging to the first group are usually incisors or bicuspids. An extra canine tooth is a very uncommon occurrence. Heider records a remarkable case where a woman, after losing by extraction a well-developed canine, erupted in three months a small tooth, the size of a rice kernel, with its extremity covered with enamel. After the removal of this first supernumerary, a second and finally a third appeared at similar intervals. The second group resemble the canine teeth in form, though there is no danger of confounding the two. The crown with the invariable single root is conical, and in rare cases the crown may be pyramidally three-sided. Their locality is variable—either in the arch, or more generally within the arch. Their eruption takes place during the first or second dentition, or in the interval between the two. Sir John Tomes records two cases in children of five years. In most cases they belong to the second dentition and are permanent. The question as to whether they are secondary developments from the germs of milk or permanent teeth may be answered negatively, inasmuch as they differ in shape from normal teeth. Reasoning from this latter point of view, it is more probable that they are independent dental germs, products of the superficial mucous membrane, and do not originate, like the permanent teeth, from secondary germs. The upper canine teeth, more frequently than any others, are the subjects of total displacement.

Uniocular Triplopia.—Mr. WHERRY said that this was the case of a patient who, under certain conditions, while using only one eye, saw a single object appear as three. A well-known biologist and good observer, about thirty years of age, told him that after working with the microscope—which he always used with the *right* eye—he lost sight with the *left*, especially for distance, and objects seen near were multiplied. This condition would pass away after some hours. On Oct. 17th, 1885, after working with the microscope with the right eye, he paid him a visit and described a single circle on a white ground, when seen with the left eye only, appearing as distinctly three rings. The circles were sketched at Mr. Wherry's request, intersecting, though sometimes they were quite separate. The object was held at 2′ distance, further off was not multiplied, and nearer was blurred.

L. V. = $\frac{20}{60}$: cyl. − 0·75 *D.* − *V.* = $\frac{20}{15}$ easily.
R. V. = $\frac{20}{30}$: − 0·75 *D* *V.* = $\frac{20}{20}$

Ophthalmoscope shows a thin irregular atrophic crescent at each *o. n.*, otherwise normal. On Oct. 20th, after two days' rest from microscope work,

L. V. = $\frac{20}{30}$ improved with − 0·75 *D.* to $\frac{20}{15}$.
Rt. V. = $\frac{20}{40}$ easily: improved with − 0·75 *D* to $\frac{20}{20}$,

and the defect in sight and multiplication of images is no longer complained of. There was nothing to be discovered abnormal in the eyes except what was mentioned. The patient suffered from habitual constipation, and lately from fissure of the anus. Mr. Wherry said this was probably a case of ciliary spasm; it was curious that the eye which multiplied the image was not the eye which was used in microscope work. It was not unlike the case of uniocular diplopia which occurred in an amateur astronomer, and was reported by him to the Society in December, 1883.

Remarkable Fit after a Fall.—Mr. WHERRY also related the case of an athletic young man, who fell over a rope on to grass, picked himself up, made a remark, and then went off into an apparently unconscious state; was carried by his friends into the nearest shelter, and was laid on a table in a large room. When Mr. Wherry arrived the patient was surrounded by about twenty sympathising friends; his right elbow, supposed to have been hurt, was being supported, and he lay on his back; face flushed; eyes closed; apparently unconscious. Limbs and joints seemed perfectly sound; the right arm was rigidly fixed in extension; the little finger flexed forcibly into the palm. Some slight facial contortions occurred when the lower cervical spine was pressed upon. The eyes seemed closed by effort; the pupils active and equal. Did not speak or answer questions. When asked if he had walked after the fall, and if the right leg had been stiff like the arm, a strong rigidity immediately occurred in the right lower limb. In about twenty minutes he answered a question with a short grunt. Was put to bed; passed urine eight hours after the fall, about eleven hours after his lunch. He gradually recovered in about three days. There was a history of a severe fall, while steeplechasing, two years before, and he was said to have been unconscious for days, followed by frontal headaches of a severe kind. This may be looked upon as a so-called "hysterical" fit. The influence of suggestion in stiffening the right lower limb, and perhaps also the elbow, is worth noting. The rigidity was very marked, the muscles becoming hard, and the right limbs resisting all attempts at flexion. Careful examinations failed to detect any lesion, not even bruise or swelling of the skin.

The following specimens were also shown by Mr. Wherry: Fatty Tumour of the Tongue; Horny growth from face.

Notices of Books.

Ein Beitrag zu den Operationen der Cephalocelen (A Contribution to the Operative Treatment of Cephalocele). Pp. 33. By Dr. BERTHOLD FLOTHMANN. Berlin: Henser.—This *brochure* contains the account of a case of cephalocele which was successfully treated by excision, the child dying eighteen months later of hydrocephalus. A needle armed with stout silk was passed through the centre of the pedicle, which was now tied in two halves; the tumour was then cut off, and, after tying one artery, the edges of the wound were carefully brought together with twelve sutures. An iodoform dressing was applied. There was little or no reaction, union being perfect on the third or fourth day, when the stitches were removed. The sac contained a serous, slightly blood-stained, albuminoid fluid, with a specific gravity of 1006. The interior of the sac wall was for the most part smooth; but presented near its attachment a somewhat villous appearance. There are figures representing the case before and after operation, as also the microscopic structure of the sac wall. The author reviews and summarises the various measures which have been adopted by different surgeons for the removal of such

Digitized by Google

cases. The occurrence of hydrocephalus after successful removal of the sac is an interesting fact, and is in keeping with the but too frequent result of obliteration of the corresponding malformation of the spinal column—i.e., spinal meningocele,—whether by removal or after injection.

The New Religio Medici (Chapters on Present-day Subjects). By FREDERICK ROBINSON, M.D. London: Elliot Stock.—Under the above title are included a series of short critical essays dealing with certain subjects relating to religion and modes of public worship which are capable of treatment from a medical standpoint. The author is evidently well read in Scripture. His position is not that of a merely dispassionate observer, or, in modern language, Agnostic, but of a sympathetic exponent of Christian doctrine, while at the same time there is little or nothing of morbid asceticism in his belief as here expressed. The book opens with two chapters of sensible remonstrance against the monotonous formality of Sunday services as they are often conducted, supported by a protest in favour of a less automatic, more attractive, and still perfectly orthodox system. The familiar questions connected with the action of faith as a healing power are treated in a judicious manner. Then follow chapters on "The Church and the Army," on Hinton's theory of "Universality through the Flesh," &c. There are interesting and studious reflections on the origin and purpose of sickness, on "Biblical Plague and Pestilence," and on "Possession by Demons." Among the faults of the work we have noticed in some parts a certain laxity in the argument, and especially an abruptness in style, which, if concise, is rather too bare to be attractive. It is, we might say, Carlylean, without the glow of picturesqueness which gives a living force to the writings of the Puritan in letters. This defective style is partly due, no doubt, to the purely didactic nature of the purpose by which it is inspired.

Hints on the Breeding and Rearing of Farm Animals. By THOMAS WHALLEY, Principal of the Royal Veterinary College, Edinburgh. Pp. 68. Turnbull and Spears. 1887.—The little book before us is an enlarged edition of an address read before the Fife Farmer's Club on the breeding and rearing of animals. It deals with a subject of the first importance, not to farmers only, but to every resident in these islands. We must congratulate the author on having placed in so small a compass, so tersely, so simply, and yet so thoroughly, the first principles of farm-breeding before his readers. He touches upon the choice of parents, and the management they require during the breeding season; next, on the management of both parents and young at the period of parturition; and, lastly, on the management of the young subsequent to their birth. The practical farmer will find some simple but most excellent advice in this book on the subjects just mentioned. We would specially refer him to the sections which deal with cleanliness, a matter which is far too often left entirely out of his consideration. The author shows that cleanliness of the stalls, of the drinking water, of the attendants themselves, and wholesomeness of the food, are as essential items in the rearing of healthy animals as they are in the rearing of healthy human beings.

Journal of the College of Science, Imperial University, Japan. Vol. I. Part 3. Tokyo, Japan. 1887.—This part contains some very creditable work done by the professors and students in the Science College of the University of Tokyo. The first memoir is by K. Mitsukuri, the professor of zoology, and C. Tshikawa, assistant in zoology, and is upon the formation of the germinal layers in Chelonia. The material for this was obtained from M. Hattori's large hatching establishment in Honjo, a suburb of Tokyo, where hundreds of the snapping turtle (Trionyx Japonicus, Schlegel) are annually bred for culinary purposes. It may just be noted that they agree with Balfour and Hartwig in stating that the mesoblast always arises as paired masses, one on each side of the median line, and that these two masses are to be regarded as paired denticula of the alimentary canal. This memoir is illustrated with four plates. 2. S. Watase: On the Caudal and Anal Fins of Goldfishes, with two plates. 3. C. Sasaki: Some notes on the Giant Salamander of Japan (Cryptobranchus Japonicus). 4. Aikitu Tanakadate: A Coilless Pocket Galvanometer and a Flat Coil Pocket Galvanometer. 5. B. Koto: Some occurrences of Piedmontite in Japan. 6. S. Sekiya: The severe Japan Earthquake of Jan. 15th, 1887. 7. C. G. Knott: Notes on the Electric properties of Nickel and Palladium. 8. A. Tanakadate: Note on the Constants of a Lens.

Sul Laringismo Stridulo e le Convulsioni dell' Apparato Respiratorio (Laryngismus Stridulus and Respiratory Convulsions). By Dr. W. H. BARLOW. — This is a reprint from the "Archiviodi Patalogia Infantile," published in in Naples. Dr. Barlow (of the Manchester General Hospital and Dispensary for Children) discusses the causes of these convulsions, and especially points out how in artificially fed children, who so frequently suffer from gastric irritation, such convulsions are produced. The share which rickets plays in their production is referred to, though too briefly; and among the remedies he suggests, we notice that cod-liver oil is not mentioned, which, in our opinion, should be the practitioner's sheet-anchor. The *brochure* is an interesting summary of what is known on this matter.

Atlas von Beleuchtungsbildern des Trommelfells (An Atlas of the Membrana Tympani as seen through the Otoscope). By Dr. KURD BÜRKNER. Fourteen Tables in Chromolithograph. Jena: Gustav Fischer. 1886. — The author, who has charge of the ear department in the University Poliklinik at Göttingen, has published this Atlas as a complement to the many existing text-books on ear disease, and in the hope of facilitating the interpretation of what may be seen through the otoscope. The plates contain eighty-four figures, with brief descriptions. Each figure is taken from nature by the author, and the most common forms of ear disease have been selected. In conjunction with a good description of the disease, such as is furnished in many of the text-books, this Atlas will prove very useful and very acceptable, especially to those who are commencing this kind of work, as well as to such as are not within reach of special instruction.

The Common Diseases and Accidents to Life and Limb. By M. M. BASIL, M.A., M.B., C.M. Edin. London: J. and A. Churchill.—In the form of a popular lecture, Mr. Basil has contrived to convey in a readable and entertaining manner a large number of sound hints to those who may be in attendance on persons who meet with accidents or who suffer from various medical and surgical affections, including insanity. His advice is more frequently not to do things which people are in the habit of doing than to resort to a specific set of directions as to treatment, and he very properly exposes several popular fallacies. Amongst other matters, the author gives some excellent hints about the manner of "sending for the doctor."

Atti della Reale Accademia Medica di Roma. 1883-86. Vol. XII., Serie 2.—This volume of the proceedings of the Royal Medical Academy of Rome contains the following articles:—Pyelo-nephritis, by Professor Majocchi; Interparietals and Preinter-parietals of the Human Skull, by Professor Sergi; the Connexions of Muscle with Tendon, by Professor Giuliani; the Prophylaxis of Phthisis, by Drs. Celli and Quarnieri; the Development of the Sulci and Convolutions of the Brain, by Dr. Mingazzini; some Statistics of Disease in Rome, by Professor Scalzi; the Chemical Reactions of Vibratile Cilia, by Dr. Bocci; and the Blue Pigment of Physalia Pelagica, by Professor Colasanti. These papers are many of them of considerable interest, especially when read with the assistance of the plates and diagrams which accompany them.

Analytical Records.

ALPINE MILK GUARANTEED FREE FROM SUGAR OR ANY OTHER FOREIGN SUBSTANCE.

(FIRST SWISS ALPINE MILK EXPORTING COMPANY, SWITZERLAND.)

ANALYSIS showed that this article is genuine condensed milk. It contains no trace of added sugar, or of boracic or salicylic acid. Diluted with two parts of water it gives a milk rather above the English standard—that is to say, a milk which, although not very rich, is rich enough for domestic use. The direction on the label is that three parts of water are to be added. This would give rather a poor milk, which would contain only 8·15 per cent. of non-fatty solids, 1·97 per cent. of fat, and 0·65 per cent. of ash. It will be seen that the milk is absolutely free from adulteration. It is a valuable article, and can be used with confidence if not excessively diluted.

BON FOOD.

(BON FOOD SUPPLY COMPANY, 31, CHARLOTTE-STREET, OLD KENT-ROAD.)

A mixture of cereal and leguminous flour with a small quantity of sugar. It is well prepared, and is a highly nutritious and convenient form of food. It is well adapted for domestic purposes, and can be used with advantage for puddings, custard, and porridge. It is needless to add that it is highly nitrogenous.

LEMONETTE.

(WILLIAM WHYSALL, GRANTHAM.)

We have before noticed with approval Mr. Whysall's preparations. The present is an excellent non-alcoholic beverage, quite free from lead and other poisonous metals and from mineral acids; 100 cubic centimetres contained acid equivalent to 1·673 grammes of citric acid, which is a fair proportion.

LOCK'S BEEF EXTRACT.

The sample we examined contained the following:—

Water, expelled at 212° F.	64·5
Organic constituents	32·0
Ash (phosphates, &c.)	3·5
	100·0

Beef-tea made from it was good in flavour. Finely divided fibre was found to be present in considerable quantity. The preparation evidently contains the whole of the meat, and as such is of great nutritive value.

RUSSIAN CAVIARE.

(CH. H. SENN, 329, VAUXHALL-BRIDGE-ROAD.)

This is pressed caviare of excellent quality. Ordinary caviare is so very oily that many who like the taste cannot eat it. Pressing removes much of the oil and improves the flavour in a remarkable degree. We recommend all who are benefited by cod-liver oil to try pressed, if not unpressed, caviare on buttered toast with a little lemon. It is unnecessary to commend it to the epicure.

TABLE DELICACIES: POTTED FOIE GRAS, DEVILLED TONGUE, SARDINE PASTE.

(CH. H. SENN, 329, VAUXHALL-BRIDGE-ROAD.)

All that the analyst can say of these preparations is that they are well made and free from adulteration. That they are excellent in flavour the public will soon discover.

BROMIDINE (BORLAND'S PATENT DISINFECTANT, ANTISEPTIC, AND DEODORISER).

(MAY & BAKER, BATTERSEA, LONDON).

The value of bromine as a disinfectant is admitted by all, and this preparation is certainly a most convenient source of the element. The white powder has merely to be moistened with water, and bromine vapour is given off in abundance. Following the printed directions, we took as much of the powder as would lie on a penny, and, treating it with water, found that six grains of bromine were liberated. There is no trouble or risk of failure in the use of the preparation, and it is certain that bromine could not be so easily generated in any other way.

LIQUOR PODOPHYLLIN ET PEPSIN (HOCKIN).

(HOCKIN, WILSON, & CO., DUKE-STREET, MANCHESTER-SQUARE.)

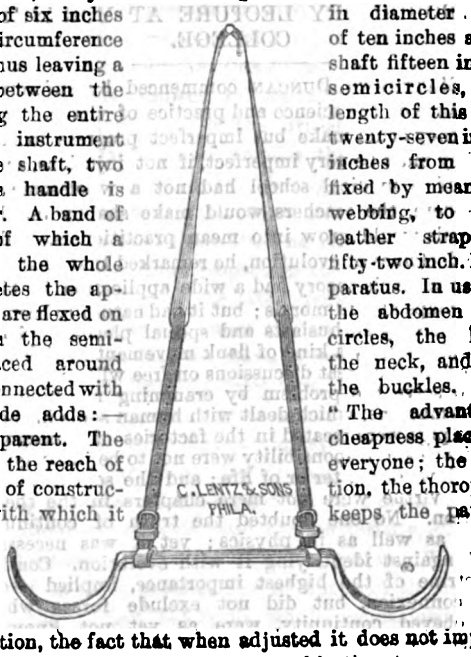
Hockin's well-known liq. podophyllin is now associated with pepsin. In such a mixture all depends on the quality of the pepsin, and as we find by experiment that a small quantity of the liquid dissolves a considerable quantity of starch paste, we have no hesitation in recommending it. Hockin's podophyllin and pepsin is a trustworthy preparation.

LIQUOR PODOPHYLLIN ET BELLADONNA C. STRYCHNIA (HOCKIN).

(HOCKIN, WILSON, & CO., DUKE-STREET, MANCHESTER-SQUARE).

This, like the last, is a genuine and reliable preparation, suitable for hepatic and intestinal derangements. The strychnine can be extracted by ether, and is recognised easily by the bitter taste and the bichromate test. Each drachm of the mixture contains one-fourth of a grain of podophyllin resin, one-eighth of a grain of extract of belladonna, and one-thirtieth of a grain of strychnine.

TETT'S LILY TABLET.



(F. G. TETT, 80, CARLTON-STREET, KENTISH TOWN).

This is a white, solid cake, smelling of camphor and slightly perfumed. It is not a soap, but is intended for use after washing. The presence of camphor is readily detected by careful sublimation, and the residue saponifies easily with potash, white fatty acid separating from the soap on the addition of acid. It is a pure and elegant toilet preparation, well adapted for softening the skin.

New Inventions.

APPARATUS FOR MAINTAINING THE LITHOTOMY POSITION.

THE apparatus figured in the woodcut was designed by Dr. McBride, of Philadelphia, to enable the surgeon to keep his patient in the exact lithotomy position during the performance of operations on the perineum or neighbouring parts. "It consists of a piece of hard elastic wood, ash, hickory, or white oak, one inch wide, three-eighths of an inch thick, thirty-six inches long, bent at each end in a semicircle of six inches in diameter or a semi-circumference of ten inches and a half, thus leaving a shaft fifteen inches long between the semicircles, and making the entire length of this part of the instrument twenty-seven inch." To the shaft, two inches from each end, a handle is fixed by means of leather. A band of webbing, to each end of which a leather strap is sewed, the whole fifty-two inch. long, completes the apparatus. In use the thighs are flexed on the abdomen and put in the semicircles, the hand is placed around the neck, and the ends connected with the buckles. Dr. Mc Bride adds:—"The advantages are apparent. The cheapness places it within the reach of everyone; the simplicity of construction, the thoroughness with which it keeps the patient

in position, the fact that when adjusted it does not impede the circulation, which is the great objection to so many similar inventions, the lightness and strength, render it a valuable acquisition to the surgeon and gynæcologist."

THE "NELATON" PATENT VALVE SYRINGE TUBE.

THIS syringe tube has been introduced to supersede those generally in use on account of two special features. First of all it is perfectly flexible; then, instead of the usual aperture, it has several fine slits which open out when fluid is forced into the tube, but are quite closed and almost imperceptible at other times. The flexibility of such a tube

is a matter of the very highest importance; the number of accidents that have occurred, even to trained nurses, from the use of ivory and other rigid enema tubes is so large that they ought to be universally abandoned. It is also well known that unless great care is taken in its manufacture, the common large aperture in a rubber tube may be a cause of a great deal of pain to the patient. This cannot arise when such a tube as the "Nelaton" is used.

NEW UTERINE SUPPORT FOR EQUESTRIENNES.

SHORTLY after my association with the Wild West I asked the frontier girls whether the violent riding did not shake them considerably, and was told that at times they suffered a great deal of pain. I advised them to get abdominal belts for support whilst riding; they did so, and felt great benefit therefrom. On talking the matter over with Mr. E. Huxley, of Old Cavendish-street, he suggested a uterine support, which consists of a peculiar shaped pad with two straps which cross over the sacrum, and are brought to the front and fastened with any amount of tightness the wearer may find desirable. I got him to make one for each of the girls, and they say they are such a comfort and support that they will never ride without them. I think the belt will prove a great blessing to ladies in the hunting field, as well as to professional riders.

R. J. MAITLAND COFFIN, F.R.C.P. ED.

Baron's Court, S.W., Oct. 1887.

INTRODUCTORY LECTURE AT YORKSHIRE COLLEGE.

DR. MATTHEWS DUNCAN commenced by enforcing the importance of the science and practice of virtue. Without virtue they could make but imperfect progress in science, and they must be very imperfect, if not injurious, in practice. If a medical school had not a wholesome moral atmosphere, the teachers would make shabby pupils, and the pupils would grow into mean practitioners. Alluding to the doctrines of evolution, he remarked that that charming and valuable theory had a wide application in biology, and perhaps also in morals; but it had naturally been forced to extremes by enthusiasts and special pleaders. To such, it would seem, by a kind of flank movement in dialectics, to render vain the great discussions on free will and necessity, and to solve the problem by cramming mankind into a fatalist machine, which dealt with human souls in the same way as pigs were treated in the factories of Chicago. But conscience and responsibility were not to be justly governed by the laws of matter or of life; and the science and practice of virtue were not mere chapters in the theory of evolution. No one doubted the truth of continuity in morals as well as in physics; yet it was necessary to guard against identifying it with evolution. Continuity, a doctrine of the highest importance, implied sequence with connexion, but did not exclude forces which, if they obeyed continuity, were as yet not known, but only suspected to do so. No one doubted the continuity of the prevalence of scarlet fever. It was always among us, carrying off its victims at, at least, an average rate. But that continuity, with its average, was violently disturbed—not utterly broken—by the unaccountable appearance of epidemics, which despised the average and raged according to a different law. So, in politics, there was a continuity, but it was disturbed by a Cæsar, a Charlemagne, or a Napoleon. So, in the science of medicine, continuity was modified by a Lavoisier, a Bichat, or a Schwann. So, in the practice of medicine, continuity had its uniformity of course interfered with by a Hippocrates, a Galen, or a Cullen. The appearance of a great original genius in medicine was a matter equally beyond their powers of explanation or control. It appeared to infringe the law of continuity, as that law was known to them by the general progress of professional knowledge. Every sane man, and every sane school, provided according to the known laws of continuity. No sane man conducted his education as that of a great original genius. No wise school provided for other than the average intellect. But this provision, according to the law of continuity, with its averages, did not imply flat sameness, or absence of genius in individuals, or the uselessness of individual effort. Were such perversion of the laws of continuity into the fatalist form of evolution sanctioned, then individual effort, if not utterly useless, would be at least discouraged or paralysed, and his remarks would be baneful and misleading. Medical students had to study the continuity of their individual lives, the continuity of their social lives, as members of a school, and the continuity of their social lives as members of a professicn. By individual effort they must push this way and that, always taking care that the direction was to higher and better. They should aim at accumulation of knowledge, acquisition of skill, and improvement in virtue, the last being paramount, and bringing all the rest in its train. Having glanced at the advantages which students now possessed as compared with those obtainable 100 years ago, Dr. Duncan said the amount of knowledge was always increasing, and with it the amount of time needful for its acquirement. Not long ago three years were enough. Now four were required, and it looked as if it would soon rise to five. Every medical school should keep the university ideal before it, and this was implied in their Leeds school being now in process of incorporation with a rising university. In the universities of Scotland and Ireland that ideal was maintained. No medical school had a more interesting or more honourable history than that of Leeds—a history that plainly indicated vigorous life, and showed great rapidity of healthy growth. Started in an imperfect form, not much more than half a century ago, by the wise enthusiasm of a few medical men in the town, it had grown into a completely equipped and recognised medical school, and, already forming part of the Yorkshire College, it would soon, he understood, be completely incorporated with the prosperous Victoria University. They might well be proud of the nursery in which they were reared and passed on to the ranks of the medical profession.

"IS CANCER CONTAGIOUS?"

To the Editors of THE LANCET.

SIRS,—The interesting question is raised in an annotation in THE LANCET of this day as to whether cancer is contagious. M. Duplouy's case certainly gives some grounds for believing that it is so. I daresay it has fallen to the lot of others, more than it has to my own, to observe with regard to this disease equally remarkable "coincidences." And I venture to say that if to such experiences as M. Duplouy's publicity were given, they might prove a means of elucidating valuable facts with regard to this insidious disease. A case of this kind came to my knowledge some time ago, the particulars of which, I think, are worth relating briefly.

A member of the medical profession married a lady who was subsequently found to labour under mammary and uterine cancer, from which she soon died; not long afterwards the gentleman himself, who had previously been healthy, developed symptoms of cancer, which disease subsequently became localised in the stomach and liver. Before his death he again married, and a year or so later the second wife was under the necessity of having both mammæ removed for cancer, in successive operations, and she sank after the second operation.

I am, Sirs, your obedient servant,

Harley-street, W., Oct. 8th, 1887. JAMES ADAM, M.D.

THE LANCET.

LONDON. SATURDAY, OCTOBER 15, 1887.

THE decision of the International Hygienic Congress to hold their next meeting in London makes their recent proceedings in Vienna of especial interest to Englishmen. It has only of late years been possible to regard the subject of hygiene as one fitted for international consideration. The complete neglect of sanitation in some countries and its imperfect recognition in others proved that its relation to national prosperity was not sufficiently understood, and suggested that no general European interest would be felt in the discussion of conditions affecting health. By degrees knowledge has increased, and, taught by the sad experiences of the last few years, the more enlightened nations have turned their attention to methods of preventing disease. As a result the Congress at Vienna brought together nearly three thousand people from all parts of the globe, and papers were read and discussed in a manner which proved that a higher value attached to health than heretofore. This was especially seen in the demand for legislative control which was put forward by many who took part in the proceedings at Vienna. Interference with the freedom of personal action is more readily accepted on the Continent than in England, and it is but natural that those who have satisfied themselves of the advantages which legislation on one point or another would confer on communities should thus wish to enforce their doctrines. But the Congress showed, as all Congresses show, that if the opinion of the many is to be made the basis of legislation there would at times be the greatest amount of interference with the least amount of good. The Vienna meetings will serve the double purpose of indicating the necessity of skilled investigation of the causes of disease, and of encouraging statesmen to rely upon work of this character rather than upon collective opinion.

The excellent work which is carried on in the continental laboratories has undoubtedly had its effect in teaching the value of exact knowledge, but there was none the less too great a desire at Vienna to record by resolution the opinion of numbers, regardless of their fitness to exercise any proper judgment upon the points at issue. This was especially objectionable when the subject had any reference to the practice of different nations. In meetings composed in greater part of members of one race and of one way of thinking, it was impossible that decisions should not depend upon this circumstance, and any attempt to express an international feeling, whatever it might be worth, was therefore certain to lead to an untrustworthy result. In the Congress to be held in London this would be still more undesirable. In some respects England is far in advance of other countries; she has been the subject of numerous experiments extending over many years, and the experience thus bought has placed her sanitary administration on a more secure footing. It would be impossible to prevent English feeling unduly preponderating if collective opinions were sought at meetings in London, and it will be well to guard against any action that would place the members of other nations at a disadvantage.

The best work of the Congress is educational. The excellent paper of M. EMILE TRÉLAT of Paris will certainly do much to encourage a study of the principles which should guide architects and local authorities in the building of houses and the laying out of streets. The accumulation of evidence in papers read before the Congress that cholera is disseminated by human intercourse, and especially by the fouling of water supplies, will give impetus to the improvement of localities which may now give opportunity for the propagation of this disease. It is by work of this nature that the teaching of peoples can be best effected, and the fact that all nations are alike interested in the questions which affect life is the best promise that their study will progress.

IN an able and interesting article published in the *Fortnightly Review* Mr. CHARLES ROBERTS deals with the question of the physical degeneracy of our town populations. The inquiry is for obvious reasons chiefly concerned with the condition of the labouring classes, though, in contrasting variations of death-rate, average weight, stature, and the like, there is an inseparable reference to the vital state of whole communities, without regard to rank. The author of this paper, we are pleased to note, is not one of those prophets of evil in whose eyes the future of our poorer townsfolk wears only an aspect of unbroken gloom. It is true he does not ignore the fact that causes hostile to the natural and vigorous development of human life are more largely present in cities than in rural districts; but while admitting this, he justly objects to the wholesale acceptance of evidence derived from statistics which are still necessarily imperfect, and he acknowledges the certain past and probable future success of efforts in the direction of sanitary reform. Among the signs of a progressive degradation of the national type as found in towns have been classed the diseases and infirmities of constitution exposed in examinations of recruits enlisted for the army at the present day as compared with those of twenty-five years ago. Sir THOMAS CRAWFORD entered at some length into this subject in an address delivered at the last annual meeting of the British Medical Association. While granting the premiss that the number of rejections on the score of bodily unfitness in the period 1860-64 amounted to 371·67 per 1000, and in the years 1882-86 to 415·58 per 1000, he refuses to accept the adverse conclusion drawn respecting the physical condition of men enlisted during the latter period, and chiefly in towns, inevitable as that may at first sight appear. In dealing with these data we must, as he says, take account of the fact that formerly rejections were not officially notified with the same strictness as they now are, and also that under the present short-service system allowance has to be made for a larger number of half-grown youths provisionally recruited without previous examination. These qualifications of necessity, and very materially, affect the value as evidence of the statistics in question. We doubt, indeed, if on other grounds the relevancy of the latter as regards the subject before us can be maintained. On a comparison of the two tables, it is at once evident that certain particulars of health, which are noted and have

Digitized by Google

their numerical equivalent in the later, are not even mentioned in the earlier; and, what is of even greater consequence, in the list of failures included under the former category, deficient weight, chest measurement, height, and erroneous age go far to swell the total, while there is decidedly less evidence of serious bodily disease or deformity. The recruit, if smaller, is healthier and better made; and while we cannot deny the important significance of diminished size, neither can we, in the face of a frequent miscalculation of age, of which there is ample evidence, resist the impression that youths have in many instances been enlisted instead of men. Statistics of this character have consequently the less value as bearing on the condition of the adult population. The whole argument, as far as it rests upon this kind of proof, is as yet quite unripe for accurate decision; and while therefore we must be careful not to ignore the suggestive note of warning thus conveyed, we must equally avoid any tendency to pessimism, founded on such insufficient data. If, again, we turn for information to strictly civil life, there is no lack of circumstances which obviously tend towards deterioration. Measures of sanitation have not certainly among the masses inhabiting our larger towns arrived at that perfection which is desirable. Physical energy is far too often overwrought, and the conditions of daily work are too commonly insalutary. Improvement in this direction is, however, steadily progressive. There is also an increasing tendency on the part of employers to allow, and on the part of the employed to accept and utilise, some hours of the working week for purposes of recreation. Physical exercises are, as a consequence, viewed with increasing favour, and, whether for child or man, are winning their natural place among our national necessities. It was never, indeed, to be expected that they would cease to be regarded with favour. The sole fear was that their right of observance might be swallowed up by the more urgent claims of labour, and this fortunately the common sense of public opinion is not likely to allow. The food question, though probably incapable of a wholly satisfactory solution, occupies a position much advanced beyond that which it held in the earlier half of the present century. The influence of this and other allied matters of nearly equal moment, a decided and general rise in wages, diminished cost of clothing, of house-rental, and of living as a whole, have, as Mr. ROBERTS observes, exercised a most beneficial effect in checking that process of retrograde change which many regard, not without a reason, as a possibility of the future. Thus far, however, we feel a certain satisfaction that the evil of decadence is more visionary than real, but at the same time we must recognise the practical truth that continued future prosperity is compatible only with a vigilant observance of those laws of healthy life which nature constantly defends by imposing on those who disregard them the penalties of physical enfeeblement and final extinction.

THE French, imaginative and inventive as ever, are, generally speaking, more suggestive and less matter of fact than most other nations. Take, for instance, the subject of Hystero-saturnine Paralysis, which has created considerable interest in French papers of late. Hysteria engendered by lead poisoning may produce sensory and motor paralyses having all the essential characters of ordinary hysteria. Such paralyses must therefore be regarded as of genuine hysterical nature. We believe that these propositions express the central idea of those who have lately written on the question; certainly of M. POTAIN, whose contribution may be read in *Le Bulletin Médical*, No 54. The case recorded there was that of a man aged twenty, a house painter by occupation, who had followed his calling for eight years. He suffered on three separate occasions from lead colic, the last occasion being in 1885. About the same time he was also the subject of an attack of typhoid fever. But beyond these illnesses he had never suffered from any complaint, and certainly not from nervous morbid phenomena, being neither more irritable nor more emotional than the common run of men; nor had his sleep ever been disturbed by night terrors or by nightmares. Finally, he does not seem to have committed any excesses either in venery or alcoholism. In the family history a slight neuropathic disposition appears to exist.

Fifteen days before his admission to hospital the patient experienced in his right arm, without any apparent reason, an increasing weakness, which gradually progressed to the point of complete wrist-drop. The treatment pursued in the hospital consisted in the employment of faradisation, iodide of potassium, and sulphur baths, but no definite improvement resulted to the paralysed member. There was total inability to extend the fingers or the wrist, and he had no power of abducting or adducting the wrist joint. The flexion of the forearm upon the arm was voluntarily possible, and in this movement the long supinator manifestly joined, although its contraction was feebler than that of the sound limb. *The paralysed extensor muscles of the forearm contracted energetically on the application of the faradaic current*, more energetically and more rapidly than the muscles of the sound arm did to the same strength of current. It was further observed that the patient bore with equanimity and without apprehension or pain the most powerful faradaic shocks on the paralysed limb, again contrasting strongly with the opposite limb. From time to time complaint was made of cramps in the legs, and further investigation discovered that there was anæsthesia of the right side of the body, and of a typical hysterical sort. The tactile sensibility was diminished, painful sensations were not felt at all, and sensations of heat were scarcely recognised, and to them he certainly made no resistance. There was no loss of colour-vision, or any disturbance of the same, but the acuteness of vision was blunted, and the diameter of the visual field of the right eye measured but one-half of that of the left. The acuity of hearing was likewise lowered in the same degree as that of vision, and on the same side. But although the olfactory sense was diminished on the right side, there did not appear to be any defect of the sense of taste proper. A slight but definite "lead line" was detected at the base of the canine teeth. The difference in the grasps of the two hands was represented by the numbers 9 for the right and 31 for the left hand. The right hand and forearm were also colder than the left. A horseshoe magnet was applied to the outside of the right forearm, and its application continued for forty-eight hours, at the end of which time the paralysis was found to have changed sides, as in ordinary cases of *transfer*. A few days later the para-

Digitized by Google

lysis almost entirely disappeared, but some of the symptoms remained longer, though lessened in degree.

It is perhaps not assuming too much to suppose that many practitioners would have been contented in this case to diagnose the presence of lead paralysis; but the anæsthesia and the character of the electrical reactions, together with the precise distribution of the paralysis, form a group of conditions sufficiently antagonistic to such a diagnosis.

The chief lesson to be inculcated in cases of the kind is the necessity of recognising the fact that diseases of different kinds may coexist and progress together in one and the same organism, and we should admit the possibility of this combination whenever any unusual circumstance is evident in a case in which the probability is great that the two or more lesions are results of the same morbid agent. If a patient has a rash on the body suggestive of syphilis, and has also vague symptoms of nervous disease which may be syphilitic, the most probable diagnosis is that the nervous lesion is also syphilitic; but we must allow that other causes may also be acting, aiding and abetting the syphilitic cause, and such causes will frequently be found to be either lead, alcohol, or mercury. We may remark, in conclusion, that LETULLE and others believe mercury may be a cause of hysteria, and that syphilitic patients with nervous tremors may confront the practitioner who attributes the movements to syphilis, when in some cases it is evident from further inquiry that a long mercurial or iodide treatment may have had some share in the causation of the abnormal movements.

THE nature and limitations of the protection of the Leicester community from small-pox is now pretty well understood. Even the sanitary authorities of Leicester dare not yet—as our Commissioner has shown—face the awful disease without the protection of vaccination, and generally of revaccination or previous small-pox. This protection the sanitary authorities, as a whole, have done much to disparage, so that they boast of an enormous number of absolutely unprotected persons. The only security of such persons is living in Leicester, and this only holds so long as vaccinated persons can be found to face importations of small-pox, and the importations themselves are few and far between. It is conceivable that the authorities in Leicester may carry their detraction of vaccination so far that vaccinated persons will not be forthcoming to stand between the plague and the people as at present; or small-pox may not always be so much in abeyance as now—not having caused one death in Greater London for a month past or more, and most of the twenty-eight greater towns being equally free. There is no great virtue in not contracting small-pox when it is so scarce. But some day it may rage as a fire, and Leicester people will be apt to find that they have been living in a fool's paradise. The authorities do not promise them any security outside of Leicester. Their policy may be compared to that of a father who, to save his children from being drowned, denounces swimming, and thinks to keep them from going to the seaside. All that need be said now is that intelligent unvaccinated people in Leicester—if such an expression be permissible—have no excuse for being deceived as to the limitations of their protection. All the sanitation in the world will not make small-pox anything else than small-pox, any more than it will make arsenic less than arsenic. All the admirable sanitary police arrangements of Leicester—to which our Commissioners did justice—will not avail one of its citizens who happens to stray into a neighbouring town where small-pox rages. And here we propose for the present to leave this subject. It is a mistake to throw threats and warnings away. The occasion of our breaking silence was the remark of Mr. BIGGS that by sanitary measures alone small-pox had been stamped out, omitting all mention of vaccination-protected persons. This was too much for our patience after having been at special pains to ascertain the facts. But having reminded the public of the system which we explained last year, we leave the subject, well satisfied to leave violations of law and common sense to speak for themselves.

Annotations.

"Ne quid nimis."

SIR DYCE DUCKWORTH ON PHARMACY.

THE introductory address of the session was delivered by Sir Dyce Duckworth at the School of Pharmacy on the 5th inst., and right well did the lecturer acquit himself. There was a high conservatism in his views of pharmacy and prescribing; a misgiving about our new-fangled remedies and combinations of food and physic in all sorts of forms; but withal a very hearty recognition of the services rendered to medicine by the professors of the School of Pharmacy and its members generally. He expressed the opinion that the higher the proper education of a druggist, the less likely he was to forget his own duties and trespass on those of the medical man. Referring to recent legislation and the action of the Medical Council in perpetuating the Apothecaries' Society, he expressed dissent, and the belief that the need for apothecaries had now wellnigh ceased, and, indeed, that medical men had now too much to do and to think about to dispense well. Sir Dyce Duckworth does not like the exclusion of old and long-tried drugs from the Pharmacopœia, and made a feeling confession of his satisfaction, unlike Sir Henry Acland, at the retention of musk, which he largely uses. He was, on the other hand, disposed to regret that we have on our tables extra and unauthorised Pharmacopœias, though it must be admitted that they are often very useful indeed when the regular Pharmacopœia lags behind. He also mooted one or two questions of great interest to chemical manufacturers and pharmacists, such as the almost exclusive supply from Germany of such drugs as chloral hydrate and salicylate of soda, and the vast importation of the commonest drugs from America. These are questions for our pharmacists to settle. We agree with Sir Dyce Duckworth that they ought to be able to compete with either Germany or the United States.

SCARLET FEVER IN LONDON AND OTHER LARGE ENGLISH TOWNS.

DURING the thirteen weeks of last quarter the annual death-rate from scarlet fever in the twenty-eight large English towns dealt with in the Registrar-General's weekly return was equal to 0·39 per 1000 of the estimated population, corresponding with the mean rate from this disease in the same towns in the third quarter of the five years 1882-6, in which the rate ranged from 0·59 in 1883 to 0·23 in 1885. The rate in London last quarter was 0·40, while in the twenty-seven provincial towns the mean rate was 0·38, or only slightly lower. No death from scarlet fever was registered during the quarter either in Leicester or in Derby, and the lowest rates in the other towns were 0·02 in Notting-

Digitized by Google

ham, 0·06 in Sunderland, and 0·07 in Birmingham. The scarlet fever death-rate ranged upwards in the other towns to 0·59 in Preston, 0·66 in Manchester, 0·74 in Birkenhead, 0·90 in Oldham, 0·97 in Bristol, and 1·41 in Blackburn. It would be interesting to know what proportion of the fatal cases of scarlet fever in these several towns occurred in hospital. It appears from the Registrar-General's recent weekly returns that during the five weeks ending last Saturday nearly 40 per cent. of the deaths from scarlet fever occurred in hospital, showing a marked increase upon the proportions in recent years. The death-rate from scarlet fever during last quarter varied very considerably in different parts of London: it was 0·20 in the north, 0·29 in the west, 0·38 in the east, 0·46 in the central, and 0·57 in the south groups of sanitary areas. It is noteworthy that the highest rate last quarter in any of these London groups of districts was exceeded in Preston, Manchester, Birkenhead, Oldham, Bristol, and Blackburn. If the rate in South London be examined more closely, we find that it was 0·84 in Newington; 1·02 in St. Saviour's, Southwark; 1·12 in Bermondsey; 1·68 in St. George's, Southwark; and 2·73 in St. Olave's, Southwark. The sanitary authorities in Southwark should take particular note of the exceptional fatality of scarlet fever within their districts, affording evidence as it does in corroboration of the warning conveyed by the constantly high death-rates from all causes that prevail therein.

PROPOSED CHEMICAL LUNG TEST.

DR. ZALESKI, of the Dorpat Physiological Institute, has published in the *Vrach* (No. 32) an account of some researches he has been making with the object of introducing a new lung test, which may be trusted to give satisfactory results in cases where the hydrostatic test is inapplicable or of doubtful value. He suggests that, as at the moment of birth there is not only an influx of air into the lungs, but a very marked increase in the blood circulating through them, and as blood contains iron in a tolerably definite proportion, the quantity of iron found in the lungs should furnish a clue to the question as to whether the child had breathed or not. He examined the lungs of four stillborn children and of three children born alive; also those of a healthy man who had been killed by an accident. Having of course taken care that the lungs had not been subjected to any previous section or manipulation, he tied the roots and cut off the bronchi. They were then immersed in distilled water for the hydrostatic test, and, after being dried with filtering paper, they were weighed in a platinum dish, and sections were made and carefully examined. After this they were dried in a hot-air chamber at from 115° to 120° C. until they ceased to lose weight. Soda was added to the dried lung substance, also water, and the whole was dried in a water bath. The mass was then ignited in a Bunsen's burner, treated with water, and thrown on a filter, which gave no ash. The whole was then again ignited. Here, all the iron was of course, not in the filtrate. It was then heated with strong hydrochloric acid in a water bath. After the hydrochloric acid had evaporated, the residue was treated with sulphuric acid, reduced by zinc, and the iron estimated by a solution of permanganate. The result of the observations showed that the iron contained in the lungs of children that had breathed was always considerably more in proportion to their weight than in the lungs of stillborn children. The mean percentage of iron (Fe) in the lungs of the stillborn was 0·0110 of the weight of the fresh lung, and 0·0828 of that of the dried lung; whereas the mean percentage of iron in the lungs of the children who had been born alive was 0·0188 of the weight of the fresh lung, and 0·1182 of that of the dried lung. The iron in the case of the adult was still more than in that of the infants, the percentages being 0·0217 and 0·1266 of the fresh and dried lung substance respectively. In one case in which the child had lived for five days part of the left lung was found diseased, there being evidences of septic pleuritis and pneumonia. Here the diseased portion of the lung was separately examined, and found to contain a percentage of 0·0192 of iron in the fresh state, and of 0·1197 in the dry state, so that it would appear that the "iron lung test" holds good even for diseased lungs. The author has not made observations in cases where there has been profuse hæmorrhage from the cord, nor in those where putrefaction has commenced, but he thinks it probable that the test would answer here as well as when the lungs have been immersed in spirit. Of course, artificial inflation after death would not vitiate the test, as was indeed proved by one of the cases where Schultze's method of inflation was adopted five hours after stillbirth. Dr. Zaleski's "iron lung test" is evidently of too complicated a nature to be carried out by the ordinary practitioner, but in doubtful cases it would be quite practicable to preserve the lungs and send them to an expert, just as the stomach and other viscera are sent in poisoning cases. Before, however, any real value can attach to evidence deduced from it, a large number of experiments must be made by different observers, and their results collated.

BURIAL REFORM.

A MEETING of the Church of England Burial Reform Association was held at Wolverhampton on the 3rd inst., during the Church Congress week. The Mayor of Wolverhampton, Mr. Vincent Jackson, senior surgeon to the Wolverhampton and Staffordshire General Hospital, presided, and in his opening speech warmly advocated the claims of the Association, which, though promoted by members of the National Church, was unsectarian. He also observed that "its aims were not faddy, or ephemeral, or merely sentimental, but based upon the conviction that their adoption would benefit the human race. The Association was zealously endeavouring to impress upon the public that the only mode of burial of the dead which was consistent with the health of the living was that which enabled the body as quickly as possible to be brought into contact with the earth and the air, and its decomposition and its absorption effected. The best mode of burying the dead in a sanitary point of view belonged to the domain of preventive medicine. It was, therefore, the duty of medical men to become the Society's auxiliaries, and to give on all occasions the most emphatic and dogmatic counsel upon this vitally important question. The reforms required were as follows:—The coffin should be of the most perishable and lightest material, such as compressed pulp, metallic and every form of imperishable coffin being most objectionable. The interment should be as early as possible. The pall, which was an unnecessary and baneful covering, should be discarded. The burial should be in the plain earth, in conformity with the instructions of the Burial Service, 'earth to earth,' to the total disuse of vaults and bricked graves, which convert a graveyard into a heap of putrescent remains, a source of contamination of the most deadly character to surrounding wells and watercourses for all time to come." The following resolution was subsequently moved by the Mayor: "That the prevalent mode of burial is contrary to the mode plainly indicated in the Burial Service—namely, simple burial in the plain earth; and that a return to this simple mode is necessary on grounds sanitary and economic." In seconding this, Dr. Malet, medical officer of health for the borough of Wolverhampton, said that the present system of heaping bodies in graves, or, still worse, in cemented or built-up vaults, could not be too strongly condemned, tending as it did to the spreading of disease and injury to the health of those attending such burials. The resolution was unanimously adopted.

MICRO-ORGANISMS IN INHERITED SYPHILIS.

PROFESSOR DOUTRELEPONT of Bonn, writing upon this subject (*Centralbl. f. Bakteriolog.*, No. 13), reminds us that early last year Kassowitz and Kochsinger reported the detection in the organs of five cases of hereditary syphilis of streptococci, which were contained within capillaries or their vicinity. These cocci differed from those of erysipelas in their situation, and from streptococci pyogenes in that that they were not associated with suppuration. The authors refrained, however, from speculating as to their precise significance. Kolisko, who had made numerous preparations from syphilitic infants dying within a day or two after birth, had failed to find streptococci except in one case of furunculosis, and this he attributed to infection by the streptococci pyogenes. Again, Chotzen, in Neisser's clinic at Breslau, had discovered streptococci occasionally in the bones, skin, liver, and intestinal mucosa of subjects of hereditary syphilis; but he looked upon their occurrence as accidental; although there is no doubt these particular microbes are different from those of erysipelas and suppuration. Chotzen suggests that the cases in which they occur are instances of "mixed infection," and that a streptococcus-septicæmia may be the cause of death in many cases of hereditary syphilis. The ulcerated surfaces of the mucous membranes might conceivably be the entrance of the streptococci. Professor Doutrelepont then proceeds to give his own experience. He says that in pursuing his researches upon bacilli in syphilis he met with streptococci in papules removed from an infant that died fourteen days after birth. No lesion of bones or internal organs was found in this case. The histological examination of the affected skin showed the horny layer of the epidermis over the papules to be raised up, and between this and the rete mucosum were masses of streptococci and staphylococci, especially abundant in the hair follicles and ducts of the sebaceous glands. The cutaneous papillæ were infiltrated with small cells, especially around the vessels, and streptococci were met with here also. The bloodvessels were for the most part free from cocci, but in a few which contained blood streptococci were seen between the corpuscles. On the other hand, the lymphatic channels were blocked with the micro-organisms, some of which were even detected in the subcutaneous tissue around the sweat glands and between muscular fibres. By using special double-staining methods, Professor Doutrelepont was enabled to display in the same specimens the bacilli which have been described as characteristic of syphilis, although they occurred but sparsely. He believes that the streptococci have no relation to the syphilitic process, for he has never met with them in all his previous and numerous examinations of syphilitic products. He inclines to Chotzen's view that their presence is due to a septic infection, which the cutaneous and mucous lesions of syphilis render possible.

SELF-TREATMENT.

THERE are a great many persons with whom the treatment of their own illnesses is a familiar practice. In certain cases this is, perhaps, not unjustifiable—in those, namely, where a little knowledge of medicine is found to be useful rather than dangerous in dealing with lesser ailments, and where the means of cure are commonly safe in their action, even when they fail to effect a desired result. Care must always be taken, even in such cases, to guard against mistaken application. The position of medicinal poisons for internal use is altogether different. They have no allowable place in household therapeutics. We would caution even the members of our own profession against a too great readiness to betake themselves to such means of relief, since none can gauge his own condition and its needs so accurately as a careful and intelligent outside observer, who is able to correct subjective evidence by that of skilled examination. It is much to be regretted that these considerations are apt to be regarded as unworthy of notice. At intervals an accidental death by poisoning will awaken the public mind to a sense of the danger incurred by one who thus treats himself, often with the scantiest knowledge of that self and of the drug employed, and we may hope that the lesson thus impressed will in time be learned. Still, the sad occurrence of a week ago, when a gentleman fatally overdosed himself with laudanum and chloral, is far from unique. It may well serve as a warning proof that a general, or even a somewhat intimate, knowledge of the action of poisons is not enough to justify their use in self-treatment by persons otherwise uninstructed in medicine. The use of opium in particular is becoming much too common in the hands of others besides practitioners, and it is probable that instances in which death has thus been actually incurred bear only a very moderate proportion to those in which it has been narrowly escaped.

COMPLAINTS AGAINST HOSPITALS.

IT is to be wished that when a coroner finds himself charged with an inquiry that tends to implicate our great hospitals, he should summon the medical officers, who can explain the facts. Lately a paragraph went the round of the papers touching an inquest on a boy who had sustained a blow on the head from a cricket bat, and was in the first instance taken to St. Thomas's Hospital. Thereafter a medical practitioner was called in, who attended the case, which terminated fatally from abscess of the brain six weeks after it had been seen at the hospital. At the inquest the mother seemed to reflect on the hospital authorities for not taking her boy in, and for not examining him more thoroughly. We have been at some pains to ascertain the facts, and we learn that he was carefully examined on the last occasion of his visiting the hospital, and that no evidence of serious mischief was then found. It is certainly rather hard on house physicians and other medical officers to be blamed in their absence, and have no opportunity of defending themselves.

SCARLET FEVER IN LONDON.

THE number of cases of scarlet fever admitted into the hospitals of the Metropolitan Asylums Board showed a slight diminution during the week ending Oct. 7th. Previously to this the increase had been regular, and if we may judge by the habitual behaviour of this disease, the reduction to which we have referred does not augur that we have come near to the end of the epidemic. Probably this will not be seen until the first week in November, when it may be hoped that there will be some evidence that the climax has been reached. In the meantime the managers are learning by experience that the recent Royal Commission were well advised in believing that some 3000 beds would be required by London for the treatment of cases of fever. Already more than 1900 beds in the Board's hospitals are occupied by persons suffering from this class of disease alone, and we hear with regret that measles and chicken-pox have appeared among the convalescent patients at the Eastern and Western hospitals, and that the need for their isolation will make further demands upon the accommodation at the disposal of the Board. It is fortunate that the probability that more than one of the affections the managers have to treat will attain epidemic prevalence at one time is remote; nevertheless, some number of beds in separate wards are required for typhus and enteric fevers, and for those cases which prove not to be infectious fever, as many as 132 beds being at this moment needed for persons who have not scarlet fever. The force

Digitized by Google

of circumstances has proved plainly enough that the hospitals of the managers are no longer regarded by the public as Poor-law institutions, but as provision for infectious disease occurring amongst all classes of the community. At the same time, all the parishes have not agreed to consider these institutions as part of the metropolitan sanitary administration; some still cling to the idea that it is well to maintain the cumbersome machinery which is required for the admission of the sick into Poor-law infirmaries, and insist upon the order of the relieving officer being obtained before the infectious person can be removed. As has been pointed out, it is time that this came to an end. If the present epidemic does no more than advance the time when London will be given a uniform sanitary administration, its occurrence will be less matter for regret. If the necessity for some better control of infectious disease is not recognised through the loss of life which has occurred, it is probable that the sum of money expended this year for hospital provision will teach this lesson to London ratepayers

WINDOW-CLEANING ACCIDENTS.

ATTENTION has been repeatedly called to the extreme risk to which servants are exposed when standing or sitting on the outside ledges of windows for the purpose of cleaning them. It should go without saying that such work is wholly unfit for female servants and they ought never to be permitted to clean the outside of windows at all. Even for men, unless they are steady, careful, and "strong"-headed, there is much danger. Yet what is to be done? The professed window-cleaners are generally reckless of carpets and paint, and the percentage of panes of glass they break, while repudiating all liability for damages on frivolous pretences, is very large; moreover, they are so arbitrary in their practices and aberrant in their arithmetic that it is a misery to employ them. Windows ought to be so constructed as regards sashes that they could be cleaned from the inside. Where this is not practicable it is better to use long-handled pads, which do not necessitate either standing or sitting on the ledges, or leaning against the too often broken or insecure frames themselves. It is lamentable that limbs and lives should be imperilled and occasionally sacrificed in the performance of a simple and quite ordinary domestic function which ought to be wholly free from risk.

NORWEGIAN LUNACY STATISTICS.

AN official report recently issued in Norway gives some interesting statistics relating to the inmates of lunatic asylums in that country. It appears that at the beginning of last year the eleven asylums dealt with in the report contained 1319 inmates, that 690 were admitted during the year, that 611 were discharged, and that 71 deaths occurred, leaving the number of inmates at the end of the year 1327. It need scarcely be pointed out that the number of the insane confined in lunatic asylums affords no clue to the number of the insane in any country. The rapid increase of the asylum population in England and Wales in recent years cannot be accepted as evidence of increase of lunacy, because we know that there has been in this country a constantly increasing proportion of the insane treated in asylums. In England 70 per cent. of the known insane are in asylums, 22 per cent. are in workhouses, and the remaining 8 per cent. reside with relatives or others out of public institutions. The proportion of all the insane is now 2·9 per 1000 of the population. If the proportion of the asylum inmates to the total insane is the same in Norway as it is in England, which is most improbable, the proportion of the insane to the population is in Norway scarcely more than a third of the proportion in England and Wales. In the Norwegian asylums the number of inmates discharged during last year (including the deaths) was 682, of which 229 were classed as recoveries, 209 as not recovered, 167 as improved, whilst the deaths numbered 71. The large proportion of "discharged not cured" seems to require explanation, as does the very low death-rate. The mean number of resident inmates in the asylums during the year was 1330, and the 71 deaths show a mortality of but 5·3 per cent., whereas the mean rate of mortality in England and Wales in the county and borough asylums in 1886 was equal to 10·4 per cent. Such figures as are furnished by this report appear to show that not only the proportion of the insane, but the rate of mortality among the insane, are considerably below the proportions prevailing in this country.

SIR JOSEPH HOOKER ON VACCINATION.

IF there is one subject which has been carefully studied, and on which there can be no two opinions, it is the advantage which results from the production of multiple vaccine vesicles. Since Marson first published the results of his observations at Highgate the experience of every small-pox hospital has taught the same story, that the duration of protection against small-pox is directly dependent upon the character of the vaccination, and especially upon the fact whether one or several vesicles were produced. Medical men will have heard with astonishment that Sir Joseph Hooker has recommended the production of one vesicle, because they are accustomed to regard his teaching in his own branch of science as deserving of confidence and respect. It was well that he should be fully answered. The letters of Dr. Buchanan and Mr. Claremont in *The Times*, and the admirable article which has appeared in that journal on this subject, have fully demonstrated the fallacy of Sir Joseph Hooker's contention. Greater efforts should be made to instruct the public upon matters which so closely concern their welfare. If Sir Joseph Hooker could be mistaken in regard to so assured a fact, how many more otherwise well-informed persons must there be who are in the same mental condition with regard to an operation to which every infant is required to submit. Much of the growth of feeling against vaccination is due to the misstatements of anti-vaccinationists remaining uncontradicted and unexplained. There is no question that medical men are too prone to regard as unimportant the frequent letters which appear discrediting vaccination, yet these have for years been exercising an influence upon many who accept their teaching, and who have come to consider vaccination in the light of a curse rather than a blessing. Our profession has duties beyond that of the treatment of disease, and the first is certainly that of teaching the public how it may be avoided.

LINGUAL "HEMIPLEGIA."

EXPERIMENTAL researches and clinical observations have conclusively proved that the lowest third of the ascending frontal convolution is concerned in the voluntary production of movements in the opposite side of the face and half of the tongue. Raymond and Artaud have collected six cases of cortical glossoplegia, or rather of divers troubles of lingual motility, due to cortical lesions of the ascending frontal convolutions, but in all the cases facial paralysis coexisted. Bernheim of Nancy has observed one case in which lingual hemiplegia was the only lesion. A young woman, aged twenty-three, was the subject of multiple sarcomatous tumours generalised throughout the body, and during the course of the illness, about one month before death, it was observed that the tongue on being protruded was thrust out to the right of the middle line. This lingual abnormality permitted the patient to swallow easily and also to articulate most words, but prevented the production of a whistling or

Digitized by Google

hissing sound. We have Bernheim's authority for stating that there were no other signs of dextral hemiplegia, unless a slight difference in the grasps in favour of the left be taken as sufficient evidence of the arm centre being involved. A fibro-plastic sarcoma into which hæmorrhage had occurred was found, measuring five or six millimetres broad and deep, and situated at the lower margin of the inferior extremity of the ascending frontal convolution, at the anterior aspect of this convolution, and six millimetres behind the sulcus which separates it from the third frontal gyrus.

THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

SINCE the meeting of the Sanitary Institute at Bolton a discussion has been going on in the public press on the question of the compulsory notification of infectious diseases. All seem agreed as to the necessity of some general measure by which such notification may be universally carried out, but there remains the important divergence of opinion as to the person who can properly be called upon to make the notification. On the one hand, we have a majority of medical officers of health contending that the system cannot be efficient unless the notification be made by the medical practitioner in attendance, and they allege that, where all medical men must act alike, there is no such thing as a patient discarding one doctor for another merely because he has acted as all his fellows would have been equally bound to act. Many also assure us, by the aid of statistics, that in several towns where the system is in vogue people do not, in consequence, avoid medical treatment. On the other hand, there is a large body of opinion amongst practitioners generally—and this includes some of those medical officers of health who combine sanitary work with the general practice of their profession—to the effect that the householder is the only person who can, without injustice, be required to make the needed notification. So long as this difference of opinion remains, it is clear that no general enactment on this subject is possible, and it will be well that matters should remain as they are, and that further experience should be obtained from such towns as now have, or may voluntarily seek, the needed compulsory powers. Apparently, those powers will only now be given on the duplicate system of requiring notification in all cases from both the medical practitioner and the householder, although where this system exists the former is, in practice, the only one from whom the information is demanded.

BREATHING SPACES AT OXFORD.

THE Oxford Local Board of Health have held a meeting to consider the report which was presented some time back on the question of the need for bye-laws as to open space about houses, and they have passed resolutions embodying a declaration that erroneous impressions have been communicated to the Local Government Board, and that they are quite prepared to amend their bye-laws provided they are not required to adopt the model code of the central authority. It is not clear on what point erroneous impressions have been brought about; for, from the description of house property which has lately been contained in the Oxford local press, it is clear that the inspectors of the Local Government Board in no way exaggerated the evils which they described; indeed, they were locally taken to task for having omitted to deal with the worst conditions prevailing in the city. That some remedy is needed, no one who knows Oxford can doubt; and we are glad to learn that the present inefficient bye-laws will be amended. We hope, however, that the amendments to be proposed will not be such that they cannot, in the interests of health, receive the needed Government sanction.

THE CROWN PRINCE OF GERMANY.

WE are glad to hear that his Imperial Highness continues to make satisfactory progress, no recurrence of the warty growth having taken place since the application of the electric cautery last June. The upper air passages, however, show a marked predisposition to catarrhal inflammation, and render it most necessary that his Imperial Highness should be in a warm climate, and, as far as possible, abstain from the use of the voice. It may be pointed out that, roughly speaking, there are two forms of chronic inflammation of the larynx: One in which the inflammatory process is confined to the mucous membrane, and gives rise to intermittent disphonia or loss of voice. This condition may last a whole lifetime without undergoing any further development. The second kind of inflammation, on the other hand, often causes interstitial changes, resulting in thickening, false excrescences, ulcerations, &c. Although the Crown Prince's affection belongs to the latter category, no unfavourable development has hitherto taken place, and the fact that his general health is very good makes it in the highest degree improbable that there should be any such untoward sequela. When Sir Morell Mackenzie left Bareno a few days ago, we understand that all was going on well, and there is every hope that, with time and care, the vocal function will be completely restored.

BRETONNEAU, TROUSSEAU, AND VELPEAU.

THE fame of the three men whose names are given above is world-wide. It is less known that they were each natives of Touraine, and it was to perpetuate this fact, and at the same time to erect a worthy memorial of them, that a movement was initiated in 1885 by the medical faculty of the Department of Indre et Loire. The result of their appeal to the medical profession and the public has been satisfactory, and on the 30th inst. the monument, which has been executed by two artists of Paris, MM. Sicard and Lalaux, will be unveiled in the Square de l'Archévêché of that city. The monument consists in an allegorical figure, holding in one hand the symbolic shield with three towers, and with the other crowning her three sons, who are represented in medallions on the top of the pedestal. The portraits are said to be excellent. The ceremony of unveiling will be accompanied by three speeches in honour of each of the scientists. Professor Duclos of Tours will speak on Bretonneau, Professsr Guyon of Paris on Velpeau, and Professor Peter of Paris on Trousseau. It may be added that Bretonneau was born at St. Georges-du-Cher in 1790, held for a long time the office of senior physician at the Tours Hospital, and died at Passy in 1862. Velpeau was born at Brédes (Indre et Loire) in 1795, and died at Paris in 1867, having been successively on the staff of St. Louis, St. Antoine, and La Pitié Hospitals. Trousseau was born at Tours in 1801, and became physician to the Hôtel Dieu, Paris, in which city he died in 1867.

THE URINE IN TABES DORSALIS.

THE following facts are set forth by MM. Livon and Alezais as the result of a series of researches on the urine of patients affected with an apyrexial disease of the cord—namely, tabes dorsalis: A tendency to diminution of the urea eliminated in the twenty-four hours; a diminution in the total daily discharge of phosphoric acid, with a tendency to proportional augmentation of the discharge of earthy phosphates; a great variation in the elimination of chlorine, with a bias in favour of hyperchloruria. Intravenous injections of tabetic urines appear to be sufficiently toxic in their action, since it has been found that from twelve to twenty-four cubic centimetres of urine per kilogramme of body weight of animals was sufficient to kill dogs.

CALISTHENICS IN LONDON BOARD SCHOOLS.

IT is highly characteristic of the backward state of public thought and feeling in respect of matters of hygiene that in the reports of the Commissioners appointed to examine into the working of the Elementary Education Acts, questions relating to the sanitary conditions and physical regimen to which school children are subjected should obtain only a very inconsiderable place. The case of starved or half-starved children has indeed forced itself into notice; but short of this, and saving only some discussion of the subject of over-pressure, points bearing upon the health of the vast school-attending community have scarcely received any attention whatever at the sittings of the Committee. Even more conspicuous than its omissions have been the shortcomings of the Committee in this respect when it has set its hand to the work. The third report, just issued, contains, for example, the evidence given by the lady who is engaged by the London School Board as superintendent of the girls' and infants' departments, and she was able to give the Commissioners some very interesting facts relating to her work in that capacity. Thus we learn that there are at present 1200 teachers within the jurisdiction of the London Board who are either trained or under training, and that physical education has been introduced into upwards of 250 schools. Furthermore, the work is being vigorously pressed on, and it is anticipated that within a period of five years there will not be a teacher who will not have received special physical training. This is as it should be, and in this respect at least the metropolis sets a good example to other urban School Board districts all over the country. The Commissioners, however, did not interrogate their witness as to the nature of the exercises in which she practises the children. It is quite needless to say that upon this will depend the whole value of the physical instruction imparted. It would seem that Ling's system affords the basis upon which the London teachers work, but it does not at all appear how much of this method they are practically able to embody in their scheme. The only question bearing upon this important matter was: "Is it a very important part that is omitted?" Answer: "The most important part, and the one which really develops the child best, is not omitted. The part which we practise with the children is the fundamental and the most necessary part." Probably that is so, but it would have been interesting to have fuller details from which an independent judgment might be formed.

SMALL-POX IN RIO DE JANEIRO.

IT is useful now and then to call attention to the ravages of small-pox in communities in which vaccination, not being compulsory, is doubtlessly much neglected among the poorer and lower classes. It appears from a monthly bulletin of mortality in the city of Rio de Janeiro for June last that out of 1170 deaths from all causes (excluding still-born) no fewer than 291 resulted from small-pox. The estimated population of the city is given as 400,000, and it may therefore be calculated that the annual death-rate from this disease in Rio during last June was equal to 8·7 per 1000. The same return shows that during the second quarter of this year 622 deaths from small-pox occurred in Rio, giving an annual rate for the three months of 6·2 per 1000. As evidence of the probable comparative neglect of infant vaccination, it may be pointed out that of the 291 deaths from small-pox in Rio in June last, 121, or 42 per cent., were of children under five years of age; whereas in England and Wales in the five years 1881-85 the proportion of deaths from small-pox occurring under five years of age, which has steadily declined with the increase of infant vaccination, did not exceed 2·3 per cent., including the cases of infants under vaccination age. With reference to this return from Rio, it may be remarked that the 1170 deaths in the city during last June were equal to an annual rate of 35·1 per 1000 of the estimated population, showing that the rate from all causes other than small-pox was 26·4. It should at the same time be stated that, with the exception of malarial fevers, which caused 70 deaths during the month, the rate of mortality from other forms of zymotic disease was not excessive. It appears that 188, or 16 per cent., of the deaths were of infants under one year of age, but the return contains no data from which the rate of infant mortality can be calculated.

THE PICTORIAL ARTS OF JAPAN.

WE learn from the *Japanese Weekly Mail* that His Majesty the Emperor of Japan has been graciously pleased to accept a copy of Mr. W. Anderson's work on "The Pictorial Arts of Japan." Many of our readers will know that Mr. W. Anderson spent several years in Japan, where he obtained a thorough knowledge of its history and studied the art of the country in all its forms. The outcome of this study appears in the work mentioned, and also in the splendid collection of Japanese art, with its catalogue, now in the British Museum. It is difficult to speak in too high terms of the excellence and artistic beauty of this work, and the reviews of it which have appeared bestow on it unstinting praise and admiration. This work, produced in the leisure of half a score of years by one engaged in the busy practice of his profession as a surgeon, is a proof of great perseverance and artistic ability, reflecting honour not only on the author, but also on the medical profession.

A NEW ELECTRO-GENERATOR.

AN important advance in the direction of producing electricity from heat is just announced from America. The inventor is the inexhaustible Mr. Edison, and his invention appears to have the merit of extreme simplicity and adaptability to a great variety of circumstances. The principle is, as often happens, so simple, that one wonders at its not having been thought out long ago. It is well known that the magnetic properties of iron are dependent, among other things, upon the temperature, and that any change in this latter involves corresponding change in the magnetic conditions of the metal. Furthermore, the effect of a change in the magnetic condition of an iron core upon the play of electric currents in its vicinity has been one of the main branches of electrical science since the time of Faraday, and is illustrated in every magneto-electric machine, of which the largest form is the gigantic "dynamo," and a smaller and more familiar form, the ordinary medical electrical machine, working with a handle, and yielding a current in quantity and tension suitable to ordinary medical purposes. In both these classes of electrical machine the current is induced in a coil of wire which surrounds an iron core, the magnetic condition of which is caused to vary rapidly by rotating a magnetic armature in its "field." Every change of magnetic potential in the core induces a current in the surrounding coil, and hence the observed results. Mr. Edison's invention dispenses with the armature altogether, and produces the desired magnetic change in the core by altering its temperature. Alternately heating and cooling his cores, which for this purpose are made hollow, he produces electrical currents in the coils analogous in every way to those which result from bringing the core under the temporary influence of a magnet. It is claimed for this invention that it will enormously simplify the production of electricity from fuel, since it will render wholly unnecessary the mechanism which has at present to be interposed between the source of heat and the magnetic core which is

Digitized by Google

to be influenced by its means. The heat will act directly on the core, and the steam or gas engine will be wanted no longer. If fuller details should justify the very rose-hued picture which has been transmitted across the Atlantic, there can be no doubt that this will prove to be an invention of incalculable value. By no means the smallest of its advantages would be the facility and economy with which it would enable us to subdivide motive power. There are numberless purposes subservient both to sanitation and convenience which demand an independent and inexpensive motor of small power. This is, indeed, one of the most pressing requirements of the day. If Mr. Edison can supply it, he will indeed deserve well of his generation, and of posterity to boot. But it is too early yet to make sure that we have here exactly what we want. The whole subject of thermo-magnetism is at present very obscure, and our knowledge, such as it is, appears to indicate that certain high critical temperatures, at least in the case of iron and most other metals, are required for the manifestation of its most conspicuous and probably most serviceable phenomena. If that is so, it may well prove that this, like some others of Mr. Edison's very ingenious inventions, is but ill adapted for any but laboratory use.

POST-GRADUATE COURSE AT CHARING-CROSS HOSPITAL.

THIS course has had a most encouraging commencement, which augurs well for its future usefulness and success. On Friday last the first lecture was delivered by Dr. Julius Pollock, F.R.C.P. (senior physician to the hospital), on the subject of Rheumatism. There were present upwards of eighty practitioners who have joined the class, and, judging by the interest they evinced by taking copious notes of the lecture, they heartily appreciated the lecturer's efforts. The vast majority of the members are men in large and successful practice, many of them University graduates, Fellows of the Colleges, or holding high positions in the Army Medical Service. Since the lecture about a dozen more have applied for admission, and the roll will soon contain one hundred names. After the lecture Dr. Pollock proceeded to the wards, and gave clinical lectures on several instructive cases. The second lecture will be delivered to-day (Friday), by Mr. Richard Barwell, F.R.C.S., on the subject of Lateral Curvature, when several typical cases will be shown.

DR. JOSEPH ROGERS.

OUR readers will be glad to learn that Dr. Joseph Rogers has so far recovered from his severe illness as to be able to use his pen. He intends to write his experiences of workhouses, which extended over a period of twenty-six years. The result ought to be interesting. Dr. Rogers's recovery is in itself a fact of interest. His condition was extreme, with heart disease, anasarca, and pleurisy. On two occasions, on the advice of Dr. Bristowe, he was aspirated with much relief.

DUST COLLECTION AT KENSAL TOWN.

MR. G. R. STRACHAN, surveyor to the Chelsea Vestry, has prepared a report showing some of the difficulties which local authorities have to face in the collection of house refuse. The contractor, having been requested to call at every house on his rounds, met with 1522 houses out of 2548 visited in the six days August 10th to August 16th where the occupants refused to allow dust to be removed. In the week ending August 23rd the number of houses visited was 3180, and at 2549 of these the dust was refused, some of the refusals being at the same houses where refusal was met with in the previous week. Thus a large proportion of householders do not want either weekly or fortnightly removal, and this even during the month of August. Mr. Strachan urges that to meet this state of things small zinc pails capable of holding only about two cubic feet of contents should replace the old brick dustbin, which is both a nuisance and inconvenient for scavenging, and that a few persons should be proceeded against under Section 126 of the Metropolis Management Act, 1855, for refusing to allow their dust to be removed.

SIR WILLIAM GULL.

WE regret to learn by telegram from Killiecrankie that Sir William Gull, Bart., is suffering from paralysis of the right side. There has been no loss of consciousness, and we are glad to be able to announce a gradual improvement in his condition.

THE IRISH COLLEGE OF SURGEONS AND APOTHECARIES' HALL.

AN abstract of the regulations controlling the conjoint examinations for the diplomas of the Royal College of Surgeons and the Apothecaries' Hall of Ireland has just been published. These bodies, as we have already intimated, are now for the first time about to hold their examinations in conjunction, by which means students can, by one series of examinations, obtain the two qualifications, and will thus be entitled to be enrolled in the Medical Register, and to enjoy all the privileges of practice in Medicine, Surgery, and Midwifery.

CHOLERA INTELLIGENCE.

THE cholera returns from Sicily fortunately indicate a decided abatement of the epidemic. Data from Messina come irregularly, and the only recent records are as to eighty fresh attacks and twenty-eight deaths between October 3rd and 8th; three deaths occurring during the same period at Palermo. No further cholera news comes from the mainland of the kingdom of Italy. From Malta there is also a history of a general diminution in the disease. It is still mainly prevalent amongst the natives in the inland villages where no such British military administration prevails as in the fortified places. The outbreak is, however, not at an end, for thirty-seven deaths occurred in the week ending October 10th.

CREOLIN v. CARBOLIC ACID.

DR. E. VON ESMARCH, assistant in the Royal Hygienic Institute of Berlin, has made a series of experiments with creolin, a new disinfectant, which has been highly spoken of by Professor Fröhner of the new Veterinary School of Berlin. Dr. von Esmarch made a number of comparative observations with carbolic acid on the disinfecting, deodorising, and antiseptic properties of creolin. Amongst other observations, he noted the effects of the two substances on fluids containing cholera, typhus, and anthrax bacilli. As a rule, creolin appeared to be much the more active. Similarly the offensive smell of various putrefying liquids was controlled much more readily by creolin than by carbolic acid. Creolin soap, too, showed itself more active as a disinfectant than corrosive sublimate soap.

EPIDEMICS ABROAD.

MEDICAL returns from Simla state that there were 30,780 deaths from cholera in the North-West Provinces during August; the disease is now normal. The yellow fever epidemic at Tampa, Florida, is reported to be abating. The recent outbreak of small-pox at Launceston, Tasmania, has been completely controlled. All the cases have been isolated, and no doubt is now felt that the disease will be effectually subdued in a short time.

ICTERUS NEONATORUM.

SILBERMANN (*Arch. f. Kinderheilk.*, Bd. 8, cited in *Fortschr. d. Med.*, No. 19) has studied the subject of icterus neonatorum, and arrived at the conclusion that it is a jaundice of reabsorption and of hepatogenous nature. The bile-stasis occurs in the bile capillaries and interlobular ducts, which are compressed by the dilated branches of the portal vein and blood-capillaries of the liver. The congestion of these vessels is brought about by the changes in the hepatic circulation that arise soon after birth, which is one effect of a general change of the blood-plasma. This blood change is a sort of fermentation depending upon the destruction of red corpuscles shortly after birth. The icterus is more marked in the more feeble infant, for in it the blood changes are more considerable than in the strong. The destruction of red corpuscles and their accumulation in the hepatic vessels afford material for the formation of bile in excess.

GUY'S HOSPITAL: TWO HUNDRED VACANT BEDS.

THE authorities of Guy's have only, so far, got £78,000 of the £100,000 for which they appealed last Christmas. Surely before Christmas comes they will have received the rest. One wonders how these 200 vacant beds, hitherto maintained by a benefactor dead for 100 years, do not haunt the dreams of our present millionaires, and beget a determination to fill every one of them.

ANTIFEBRIN AS A DISINFECTANT.

DR. S. A. VAN LEER has been prosecuting a number of researches in the Hygienic Laboratory at Groningen on the antiseptic properties of antifebrin (acetanilide). When added to milk, so as to saturate it, acetanilide prevents it from turning sour; similarly, albumen can be kept from becoming putrid. It does not, however, seem a suitable substance for dressing wounds, as it does not easily dissolve or become moist, and irritates the surface of wounds. Dr. van Leer examined the effects of solutions of antifebrin of various strengths on several kinds of bacilli, and found that the development of many of them was not by this means prevented; consequently he does not think that the suggestion of Leube to employ antifebrin for surgical dressings is likely to prove of any advantage.

FOREIGN UNIVERSITY INTELLIGENCE.

Bucharest. — Dr. Babes, Professor of Histology and Bacteriology in Buda-Pesth, accepted some time ago the invitation to a similar chair in Bucharest, he being a Roumanian by birth. The authorities seem alive to the importance of having secured so illustrious an observer, and propose to give him £1000 a year, besides which an institute is to be built, which when completed will have cost £10,000.

Kasan.—Dr. Adamyk, Professor of Ophthalmology, is about to retire. Dr. Michel Reich, a well-known ophthalmic surgeon from the Caucasus, is likely to be appointed in his place.

Kharkoff.—The Professorship of Forensic Medicine, vacant by the transference of Professor Anrep to St. Petersburg, has been filled up by the appointment of Dr. Patenko, *privat-docent* in the Military Medical Academy, St. Petersburg.

Kieff.—Dr. W. Podvinsotski has been appointed Lecturer in General Pathology in succession to Professor Chrzonszczewski.

Lemberg.—This University has no Medical Faculty, but a decree has just been issued by the Austrian Minister of Education establishing Professorships of Anatomy and Physiology in connexion with the Philosophical Faculty. This step is looked upon as precursory to the establishment of a Medical Faculty.

Vienna.—Professor Billroth, being quite restored to health, has resumed his ordinary duties.

THE MEDICAL SOCIETIES.

THE Medical Society will hold its first meeting on Monday next, October 17th, and the Royal Medical and Chirurgical Society on Tuesday, October 25th. We announced the first meetings of the other Societies in our last week's issue. The Clinical commences to-night (Friday), and the Pathological on Tuesday next.

ON the 12th inst., at the instance of the Mansion House Council on the Dwellings of the Poor, a public inquiry into the sanitary condition of Bethnal Green was opened by Mr. D. Cubitt Nichols and Mr. Shirley F. Murphy, the Commissioners appointed by the Home Secretary. After a short discussion with the counsel engaged in the case, the inquiry was adjourned for the purpose of an inspection of the streets alleged to be in an insanitary state, which the Commissioners expected would occupy at least a week.

DR. LÄNGER, *primaraerzt* of the great Vienna Hospital, after a somewhat unpleasant interview with Prof. Boehm, the newly appointed director of the hospital, took a large dose of morphia with the intention apparently of committing suicide. He was, however, promptly treated by the performance of tracheotomy and the mechanical inflation of the lungs through the opening. By this means his life has been saved. Dr. Länger, who is greatly respected, has been for some time past subject to melancholia.

THE Italian War Office, through its medico-statistical officer, Colonel Pecco, gives the following returns of the health of the army throughout the peninsula during 1885. In the military hospitals there were under treatment 160,848 men. The deaths were 2095. The mean mortality was 10·30 per 1000. The losses of recruits amounted to 2873. The number of those sent home on sick leave was 7392.

THE Aberdeen University Court, at a meeting held on Oct. 7th, appointed the following gentlemen to be extra-professorial examiners for medical graduation: Dr. J. Macdonald Brown (Edinburgh), Dr. W. D. Halliburton (London), Dr. David Lowson (Hull), Dr. Robert W. Philip, A.M. (Edinburgh), Dr. Wm. Robert Smith (London), and Dr. F. Buchanan White (Perth).

IN connexion with the Medical Society, University College, London, Sir William Roberts, M.D., F.R.S., will deliver an address in the Botanical Theatre of this College on Wednesday Oct. 19th, the subject being the Effects of Alcohol considered from the points of view of History and Natural History.

THE *Gazette* of Tuesday last announces that the Queen has been pleased to appoint William Scovell Savory, F.R.S., President of the Royal College of Surgeons of England, and surgeon to St. Bartholomew's Hospital, to be Surgeon Extraordinary to Her Majesty, in the room of Richard Quain, deceased.

AT the annual meeting of the Pharmaceutical Society of Ireland, held on Monday, Mr. James E. Brunker, M.A., was elected President, in the room of Mr. W. N. Allen, resigned. Mr. G. Lane M'Cormack was elected to a seat on the Council, vacated by the retirement of Dr. Aquilla Smith.

WE regret to have to record the somewhat sudden death, on the 7th inst., of Mr. William Trotter, the foreman printer of the advertising department of this journal. For over forty-one years Mr. Trotter had been most faithful and devoted in his service to the proprietors of THE LANCET.

Pharmacology and Therapeutics.

SACCHARIN.

THE saccharin tabloids of Burroughs, Wellcome, and Co. contain half a grain each of this new sweetening agent, which is doubtless destined to play an important *rôle* in the treatment of disease in the future. The tabloids are very convenient in form, are certainly efficient sweetening agents, and have no reducing action on Fehling's solution, thereby showing the absence of sugar. Reynolds and Branson's compressed discs of saccharin, besides containing a little carbonate of soda, have some grains of milk sugar in their composition. These reduce Fehling's solution rapidly.

EUCALINUM.

The new antiseptic poultice matrix introduced by Messrs. Rocke Tomsitt and Co. is decidedly a step in the right direction. Many practitioners object to poultices on the ground of their uncleanliness in the aseptic sense of that term, and there is sometimes ground for fear lest in dressing open wounds with poultices we may introduce pathogenic organisms. Eucalinum would tend to prevent the growth and development of such germs, whilst at the same time the added eucalyptol mitigates the sour smell which is frequently developed during the application of ordinary linseed and bread poultices.

COCA IN GASTRALGIA.

M. Ardenne, of Toulouse, states that he has found the extract of coca of great benefit in relieving gastric pain. He gives two drachms and a half during the twenty-four hours. If there is no anatomical lesion, the relief is rapid and complete. If, however, the mucous membrane is diseased, the relief is partial and temporary only. Similar results have been obtained by M. Cunéo with cocaine in cases of gastralgia with vomiting, even in those of uterine origin.

KAIRIN, THALLIN, AND ALLIED BODIES.

Kairin lowers the temperature by diminishing the production of heat, and by augmenting the radiation of the same. Its deleterious action on the red blood discs and its lowering action on the heart constitute its chief dangers. Thallin lowers the temperature by the same means, and has the same inconveniences. Hydrochinone lowers the temperature by augmenting the radiation of heat from the dilated vessels. Resorcin equally dilates the vessels, and exercises a tonic action on the heart. Antipyrin perhaps raises the blood pressure slightly, but leaves intact the red globules of the blood, whilst lowering the temperature. These are the conclusions of G. Beyer, and may be found *in extenso* in the *Deutsche Med. Zeitung*, Aug. 11th.

NAPHTHALIN IN DIARRHŒA.

Dr. Lunin, of the Elizabeth Children's Hospital in St. Petersburg, following up the remarks of Rossbach at the Wiesbaden Congress in 1884 on the value of pure naphthalin in affections of the intestinal tract, has given this drug in quantities of 7½ to 30 grains per diem, in the form of emulsion with castor oil, to children between one and five years of age with diarrhœa, with excellent results. Dr. Lunin gives, in a recent issue of the *Vrach*, a short account of ten cases in which this treatment was followed by great improvement or complete cure. He remarks that cases sometimes are met with in which naphthalin has no effect at all, and here recourse must be had to other drugs.

STRYCHNINE IN ALCOHOLISM.

Dr. Dobronravoff, who has treated a number of cases of various forms of alcoholism by hypodermic injections of strychnine, as recommended by some other Russian observers (see THE LANCET, 1886, p. 733), speaks as highly as they do of its effects. He began with the one-hundredth of a grain twice a day, and increased this dose cautiously to one-fiftieth and one-thirtieth; in one very grave case he gave one-fifteenth. He found that by this means a quiet sleep free from visions was induced in acute cases, and, in chronic forms, nausea, vomiting, and loss of appetite rapidly gave way. No evil effects could in any case be traced to the use of the drug. The total quantity given varied from a tenth to a third of a grain.

COLLODION.

The silky fibre or silk-cotton obtained from the pods of the Eriodendron anfractuosum, a plant common both in the East and West Indies, has been found to make the finest collodion possible for surgical purposes.

SALOL.

As the outcome of an examination of the results obtained by various doctors who have employed salol to reduce the temperature of many diseases, including all forms of rheumatism, typhoid fever, pneumonia, phthisis, and pleurisy, M. Ricklin concludes that it has no advantage over salicylic acid or antipyrin.

EPHEDRINE.

Chlorhydrate of Ephedrine is a new mydriatic alkaloid obtained from Ephedra vulgaris by M. Kinnossuke Minra. It has to be employed in a solution ten times more concentrated than homatropine, but it is much less costly. It does not paralyse the accommodation for near vision.

AMYLENE HYDRATE is the latest addition to the list of hypnotics; in activity it stands between chloral hydrate and paraldehyde, and is less objectionable than the latter.

PILOCARPINE has been synthetically prepared.

BROMIDE OF ETHYL is advocated by Dr. Pauschinger as an anæsthetic in minor surgical operations; it is administered in the same way as chloroform.

LITHIUM SALICYLATE is frequently contaminated with the sodium salt.

The British and Colonial Druggist (vol. xii., Nos. 5, 6, and 7) is publishing a useful table of the new antiseptic, antipyretic, and soporific remedies, drawn up by H. Helbing, apothecary to the German Hospital.

HEALTH OF THE ARMY.

No. III.

THE number of recruits medically inspected in 1885 was 72,249; and of these, 28,933 were rejected, being in the ratio of 400·5 per 1000. Of these, 57,898 were examined by army medical officers, with a rejection in the ratio of 400 per 1000, and 14,351 by civil medical practitioners. Of the latter, 198 per 1000 were rejected on primary inspection, and 185 per 1000 on secondary inspection by army medical officers, or a total of 383 per 1000. Of the recruits passed into the service, 278 were discharged as unfit within three months of enlistment, or 6·4 per 1000 of those originally found fit. The ratio of 400·5 per 1000, however, does not correctly show the proportion found unfit on medical grounds, as a certain number of recruits are included who were rejected as being "under height," "over height," and "apparent age not in accordance with general order." These are obviously military and not medical causes of rejection, and amounted to 38·6 per 1000 inspected. Deducting these and the men discharged, as above noted, under three months' service, the ratio rejected was 358 per 1000, or 10 per 1000 less than in the preceding year. The most frequent cause of rejection was "under chest measurement," amounting to one-fourth of the whole; "under weight (muscular tenuity and debility)" was assigned in one-eighth and "defective vision" in one-tenth of the rejections. The ratio of rejections was highest for infantry regiments—404 per 1000 inspected,—and lowest for the Foot Guards—314 per 1000. The proportion of recruits furnished by England and Wales was 757, by Scotland 99, by Ireland 134, and by British colonies and foreign countries 10 per 1000. The proportion of recruits between eighteen and twenty years of age was 582 per 1000—exactly the same as in the preceding year; but of these the number between eighteen and nineteen was rather higher than in 1884. The chest measurements of the recruits compare unfavourably with the preceding year, the proportion under 33 inches having been 243, as against 219, per 1000; the weight also of those inspected by army medical officers shows a reduction, the proportion under 130 lb. having been 627, as compared with 607, per 1000. There would therefore appear to have been a deterioration in the physique of the recruits for the year. There was an increase, compared with the preceding year, in the proportion of labourers and of manufacturing artisans, and a reduction in the other classes of occupations from

Digitized by Google

which recruits are drawn. As regards education, there was a decrease of 28 per 1000 in the numbers returned as well educated, and of 23 per 1000 in those unable to read, and an increase of 36 in those able to read and write, and of 15 in those able to read only. Notwithstanding the influence of board schools, there is still a sufficient number of uneducated and very imperfectly educated recruits to furnish work for the army schoolmaster. Of the recruits found fit, 922 per 1000 bore marks of vaccination, 23 of small-pox, and 55 had no satisfactory marks of either. The vaccination returns seem to be imperfect, as only 634 primary vaccinations are reported, while the number of unprotected recruits was 2372. Of the primary vaccinations, the proportion of successful cases was 577 per 1000; of 35,629 revaccinations, 466 per 1000 were successful. No information is given regarding the vaccination, and its results, of 7053 of the recruits. The value of vaccination and revaccination is shown by the fact that in a protected force of 177,928 men serving at home and abroad, only 88 cases of small-pox with 7 deaths occurred during the year; of these, 52 cases and 4 deaths were in the force employed in Egypt, so that in the rest of the force the proportion was only 21 cases and 1·78 deaths in 100,000 men.

There are a number of interesting papers in the appendix to the report. The first of these is a medical history of the frontier field force on active service in the Soudan from Nov. 27th, 1885, to Jan. 27th, 1886, by Surgeon-Major W. S. Price. The force consisted of 264 officers and 5873 non-commissioned officers and men. During the two months included in the report there were 33 admissions and 3 deaths of officers, 2 of the deaths being from wounds received in action. Among the non-commissioned officers and men, there were 1052 cases and 36 deaths, being in the *annual* ratio of 1147 and 39·26 per 1000 of strength. Nine of the deaths, 7 in and 2 out of hospital, were from injuries received in action. Upwards of one-third of the admissions into hospital were from fevers and dysentery. Enteric fever gave rise to 95 admissions and 17 deaths, being in the annual ratio of 104 and 18·54 respectively, and dysentery to 127 cases and 4 deaths, or 138 and 4·36 per 1000. No definite cause could be traced in the cases of enteric fever. On Dec. 30th the force attacked the enemy at Giniss on the right bank of the river, and completely dispersed them after a brief fight. Of the British troops, 1 officer was killed and 1 wounded, and 20 non-commissioned officers and men were wounded. Of the Egyptian troops, 1 officer and 4 men were killed and 3 officers and 11 men wounded. "The Egyptian troops behaved very well throughout." During the two months included in this report there were 3 officers and 43 men admitted on account of wounds received in action, being in the annual ratio of 73 per 1000 of strength of officers and 47 of men. One officer and 2 men were killed in action, and 1 officer and 7 men died in hospital from wounds received in action, all inflicted by firearms. Two of the deaths in action were from wounds of the head, and one of the chest; 2 of those in hospital were from wounds of the head, 4 from wounds of the chest, and 1 from a wound of the abdomen. Details of the fatal cases are given in the report.

In a report on the Abu Fatma Hospital and line of communication with the Nile Expedition, 1884-85, Surgeon-Major L Corban gives an interesting account of the arrangements made for the treatment of the sick and wounded, and for the despatch of convoys of invalids down the river to Wady Halfa. During the first five months of 1885 there were 83 officers treated, of whom 3 died, and 931 non-commissioned officers and men, of whom 25 died. The most fatal disease was enteric fever, of which there were 164 cases with 15 deaths; 129 cases of wounds were admitted, of which 2 died; 119 of dysentery, with 3 deaths. The arrangements both of the hospital and of the transport appear to have been most satisfactory. Surgeon-Major Corban reports that "the conduct of the Medical Staff Corps was excellent. Though native spirit could be purchased there was no drunkenness and only a few minor offences. Their duties, especially at Abu Fatma, working through the long trying summer months, were of a most arduous and difficult kind. The high rate of mortality and invaliding among officers and men speaks for itself. Four medical officers were invalided from the working at Abu Fatma; 2 surgeons and 7 orderlies died at their post, and are buried at this station, victims to hardship and exposure in the climate of the Soudan."

There is yet another paper connected with the health of the troops in Egypt, a report by Surgeon J. Boulger of a series of cases of small-pox among the British troops in Cairo from January to October, 1885. He gives details of 50 cases, of which 4 died. The men bore marks of vaccination, and 39 had been revaccinated with various results. The 4 fatal cases had been revaccinated, 2 unsuccessfully and 2 modified. All the mild cases, 21 in number, had good cicatrices, and "the severe cases, 12 in number, had for the most part but very indifferent marks, though some amongst them showed well depressed scars."

Brigade-Surgeon A. F. S. Clarke has furnished an excellent report on the outbreak of diphtheria in the neighbourhood of the Royal Military College at Sandhurst in October and November last. The disease prevailed in the villages of Yorktown, Camberley, and in adjacent parts of Frimley parish, chiefly among the families and domestic servants of officers, retired officers, and civilians living in these places, and therefore in close proximity to the Royal Military and Staff Colleges, but no case occurred in either of these institutions. There were altogether 88 cases between Oct. 11th and Nov. 14th, in a population of something under 4000. Of these, 18 died, 3 of them after removal from the locality. The history of the outbreak is preceded by a short but clear description of the locality in which it occurred: its soil, the health of the district, the drainage of the villages, and the water supply. The first cases occurred on Oct. 11th in two children of an officer living in Yorktown, and the wife of an officer of the Royal Military College living in "The Terrace" of the College. These were followed by many others in houses at distances varying from a quarter to two and three miles from one another, and without regularity in the attack. During the first week there were upwards of 60 cases and 10 deaths. The disease began to decline at the end of a fortnight, and the last death was registered on Nov. 10th. "The outbreak, though short, was very severe, attacking more than 40 houses of the better class, the poorer community escaping almost entirely; their cases were milder, only one death occurred among them, with the exception of a domestic servant in the house of a lady whose child was attacked." An exhaustive inquiry into the causes of the epidemic led irresistibly to the conclusion that it arose from infected milk. "Every house and even cottage where diphtheria had occurred had obtained their milk from one dairy farm. ..... Further investigation very shortly justified us in coming to the conclusion that infected milk was the *sole* cause of this outbreak." Not only were the whole of the infected houses supplied from this dairy, but in four families which did not take in this milk a case in each occurred which was clearly traced to the persons affected having drunk some of it in houses which were so supplied. The question then arose, How did the milk itself become infected? And after a very careful inquiry, the medical officers came to the conclusion that it had been caused by the use of "dangerously polluted water" in cleaning the dairy utensils. "Brushing aside, then, other theories as to the milk infection in this outbreak, we have an established fact that the water used for washing the milkcans was 'dangerously impure and polluted with sewage;' it is also just possible that the milk *may* have been diluted with this water by some servant or *employé* of the dairy." It is remarkable that cases of diphtheria occurred in thirty-two out of forty-three houses of the better classes, while there were only 5 cases in fifty cottages and artisans' houses, all supplied with milk from the same dairy. Brigade Surgeon Clark thinks this difference may be accounted for "by the fact that the poor man buys daily only a small quantity—a pennyworth or less — of milk, uses a portion in his tea, and the rest is made into a pudding for the children; they, too, generally, buy skimmed milk, which has often been scalded." The measures adopted, and fortunately with success, to present the spread of the disease to the college, were: "Officers and *employés* who had cases in their families were rigidly 'quarantined;' suspicious sore throats were at once isolated; strict attention was paid to all sanitary matters; milk and drinking water were boiled; servants were warned to report at once any illness in their families; social gatherings bringing a large concourse of people to the village were interdicted; the sanitary condition of all the buildings was carefully examined, defects pointed out, and as far as possible remedied." A good map illustrating the area of the diphtheria is attached to the report, which is of great interest and most creditable to its author, Brigade Surgeon Clarke.

In a note appended to some remarks on beri-beri, as it occurs in the Straits Settlements, by Surgeon A. A. Lyle, he gives some details of an outbreak of this disease, in the

Digitized by Google

criminal prison at Penang in 1882. It appears to have been introduced by some prisoners who arrived from Singapore by steamer, and of whom 36 out of 186 were found to be suffering from it. Although every precaution was taken and a special diet was adopted for all the prisoners, the disease spread until only 22 remained unaffected; 27 of the cases died. Among the Penang prisoners, 240 in number, 61 cases occurred, of which 12 proved fatal. Mr. Lyle believes the disease to have been propagated through excreta, but there seems some reason to connect its appearance with an inadequate supply of food, and that of an unsatisfactory character.

There is a careful and interesting paper by Surgeon R. H. Frith, on "The Relation of Malarial to Physical Causes, at Meean Meer, Punjaub, with an analysis of soil and water, and a *résumé* of meteorological observations." It would be impossible in the space at our disposal to give a useful summary of this paper, but the conclusions at which the author has arrived are thus stated:—"Malarial fevers are at their maximum in Meean Meer in September and October; this period of their greatest prevalence appearing, from an examination of the meteorological data, to be simultaneous with the termination of (1) maximum soil temperature; (2) minimum daily variation of soil temperature; (3) maximum rainfall; (4) maximum of CO_2 in the soil air; (5) maximum of humidity; (6) minimum amount of ozone in the air. The subsoil water level, the barometric pressure, and the air temperature appear from the same data to have little, or, if any, only a secondary, influence upon malarial production. . . . . The sum of our knowledge regarding the nature of malaria is very limited. We understand it merely as a subtle and unknown agent, a cause of disease known only by its effects, a product of continuous heat and moisture upon vegetable organic matter."

The usual list of operations performed at Netley Hospital during the year, with notes of the more important cases, some of which are of considerable interest, is furnished by Brigade Surgeon C. H. Y. Goodwin, the assistant professor of military surgery. We regret again to observe the Department Report issued without any contribution from the medical branch of the hospital. Surely there must, in such an establishment, be an opportunity of collecting valuable information which ought to be utilised for the benefit of the service and of the profession. We fear that the state of Professor De Chaumont's health is but too good a reason for the absence of any special sanitary communication from him.

TWELFTH CONGRESS OF THE ITALIAN MEDICAL ASSOCIATION.

CONGRESSES beget congresses. Indeed, especially abroad, they are multiplying so fast that anything like a detailed account of their proceedings must imply a readjustment of the hitherto essential conditions of existence—time and space. At Pavia, for example, the twelfth meeting of the Italian Medical Association on the 19th ult. did not close its highly interesting discussions till it had founded and organised a branch association—the Società Idrologica Nazionale (National Hydrological Society) for promoting scientific water-analysis throughout the peninsula and for obtaining Government assistance in developing its resources in mineral waters. Both these objects are in themselves highly commendable, and the latter, if attained, will do more for the prosperity of the country than any means hitherto devised for evoking its natural wealth. Italy only wants capital and enterprise to attract within her frontier thousands of the *habitués* of spas and health resorts who have long been a rich source of revenue to Germany, Switzerland, Austria, and France. The facts elicited at Pavia in the discussion that preceded the foundation of the Società Idrologica spoke eloquently for the fruitful work before it, and for the remunerative harvest it must confer on the country. Its first place of meeting will be at Bologna, some time to be yet fixed in the autumn of 1888, and its president will be Professor Chiminelli, director of the establishment at Recoaro, and its vice-president, Dr Vinai of the well-known institution at Andorno. Of the Pavia Congress it will suffice to say that in the department of surgery its papers and discussions were of exceptional interest, Drs. Bassini, Ceci, Tansini, De Paoli, and Ferrari dividing the honours of the section, De Paoli of Turin, in the course of an exhaustive communication on goitre, pointed out that the most approved modes of surgical interference with the malady were really due to Dr. Porta of Pavia, their original author and practitioner, and not, as is generally believed, to the Germans. The medico-chirurgical exposition was a great adjunct to the interest and efficiency of the Congress—the Society of the Red Cross, the Italian War Office, and many prominent firms in Italy and abroad having contributed novel and valuable additions to the *matériel* of the healing art. From the official report of the proceedings, now printing, the professional public will gather their scientific results, which by universal admission marked a signal advance on those of the previous congresses of the Association. Professor Bottini brought the meeting to a close in a congratulatory address, and the *rendezvous* for the thirteenth Congress was announced to be Padua.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF THE INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

The Sanitary State of Oswaldtwistle, by Mr. J. SPEAR. This district lies at the northern extremity of the Lancashire coal fields, and has an estimated population of 13,400. On this population the general death-rate, the deaths under one year of age, the measles, scarlatina, whooping-cough, fever, and diarrhœa death-rates are all substantially in excess of those for England and Wales as a whole. The fever is enteric fever, and when we read of defective sewers holding deposits and having inadequate ventilation, and of large, deep, sloppy middensteads of the worst northern type, together with a water-supply which should be excellent, but which is exposed to pollution from farmsteads and cottages, there is nothing to wonder at in the presence of this fever. House accommodation is fairly good in so far as commodiousness is concerned; but some houses are built back-to-back, and are dilapidated and dirty; some are built on old refuse tips; and others have but a small enclosed space, this being characterised by filth nuisances. Unfortunately the authority have been placed in great financial difficulties, and have incurred a loss of £20,000 owing to the defalcations of a clerk; but there is room for steady improvement, which need not involve an immediate disbursement of any large sum, and it is to be hoped that the recommendations annexed to the report will be accepted as a guide for future work.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Sunderland Urban District.—This borough, with a population of 127,422, had, during 1886, a birth-rate of 36·2 and a death-rate of 19·4 per 1000; the latter rate contrasting favourably with a mean rate for forty years of 24·4. Mr. A. E. Harris takes the opportunity of indicating the improvements with which this reduction has been associated, and he refers specially to the efficient and systematic cleansing of middens, ashpits, and pails. This work is done in the night, an arrangement which we believe, in most instances, to be faulty; for the cloak of darkness is not favourable to cleanly operations or to the remedy of discovered defects. Phthisis is one of the diseases the mortality of which has been lessened, and the change is attributed to the healthier conditions affecting life in the borough. The zymotic rate was also less last year than during any year as to which records are available; it amounted to 2·4 per 1000, and it involved a material diminution in the incidence of most of the infectious diseases. The notification of these diseases is in operation in this district, and is stated to have operated most beneficially. Forty cases of typhus came under notice, Sunderland being one of the districts where this disease has made its reappearance, and the occurrence calls to mind that there is still much property that needs removal in the sanitary interests of the borough. A detailed account of the current sanitary work of the district is included in Mr. Harris's report; statistical tables form an appendix, and a disease chart shows at a glance the distribution of the

Digitized by Google

principal preventable diseases that have prevailed in the borough.

Poplar.—In the south district of this metropolitan area the death-rate was 19·9 per 1000 during 1886, this being the lowest, except that for 1885, since registration began. Amongst the exceptional deaths that took place was a sudden one from lead poisoning, and Mr. F. M. Corner states that in the last three years six women from the same firm have died from the same form of poisoning, death occurring with but little previous warning. In the north district the general death-rate was as low as 15·4, and this with no less than 1·26 measles deaths, which raised the zymotic rate to 2·6. The difficulties in preventing the spread of this disease are very great, and we must look to more intelligence on the part of parents before they can be met. Referring to the number of people who prefer to sleep out of town, Mr. R. M. Talbot says that between 2 and 7 A.M. the air in the streets at the East-end is often as pure as that of many country towns, and this the more so because no fires are burning. But London is most difficult to sleep in at a time of year when the fewest fires are alight; and, besides the fact that people want to get to sleep before 2 A.M., there are other hindrances to sleep than smoke and mere impurity of air.

Holborn.—The main portions of this report relating to the health of the district are statistical. The death-rate is given as 24·4 per 1000, after the necessary corrections; but Dr. Gibbon thinks that a proper estimate of population would lower this rate. Referring to smoke abatement, he points out that there is about 15 per cent. more sunshine near Lewes than at Greenwich, the two places where record is kept, and he attributes the difference to the gross and wasteful way in which coal is consumed, and which leads to a canopy of smoke over London. At present 75 per cent. of coal is wasted in our domestic fireplaces, and he hints that instead of taking off the coal duty in London it would be well to apply it everywhere, so as to induce greater economy by the construction of proper grates.

Islington.—In this parish a death-rate of 15·7 per 1000 during the past year constituted the lowest recorded rate. It occurred in connexion with an exceptionally low birth-rate of 30·0 per 1000. Referring to the marked absence of small-pox, Dr. Tidy fears it may be the precursor of a rising wave, and he urges cleanliness and protective vaccination and revaccination, matters that are but too often neglected in non-epidemic times. Tabulation of the scarlet fever and diphtheria deaths, both for the metropolis and for Islington, shows how, with improved diagnosis, the proportional fatality of the two diseases has altogether changed; for whereas formerly the deaths from scarlatina were all but uniformly in excess of those for diphtheria, the reverse is now the case. Of 112 samples of food analysed, Dr. Tidy only found five adulterated, and in these cases the article was milk, and the vendors were prosecuted. In connexion with the general sanitary work, it is stated that under the bye-laws as to houses let in lodgings, though much has been done, it would be impossible, in the absence of a caretaker, to enforce the carrying out of the minor requirements. Having this in view, Dr. Tidy expresses the conviction that people can never be regulated into being cleanly and obedient to the laws of health. Fortunately much has already been done throughout the kingdom in this direction, and we are not without hope that the "many improvements" which even in Islington have been effected by the new regulations will not be the last result of the adoption of the code referred to.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5877 births and 3099 deaths were registered during the week ending October 8th. The annual rate of mortality in these towns, which had been 16·2 and 17·5 per 1000 in the preceding two weeks, rose again to 17·5 last week. During the thirteen weeks of last quarter the death-rate in these towns averaged 20·4 per 1000, and was 0·5 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 11·6 in Wolverhampton, 13·9 in Bradford, 14·1 in Brighton, and 14·4 in Birkenhead. The rates in the other towns ranged upwards to 24·1 in Blackburn, 24·6 in Bolton, 25·6 in Manchester and 30·1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 440 and 460 in the preceding two weeks declined last week to 412; they included 96 from scarlet fever, 95 from diarrhœa, 66 from whooping-cough, 58 from "fever" (principally enteric), 46 from measles, 38 from diphtheria, and 13 from small-pox. These zymotic diseases caused the lowest death-rates last week in Hull, Brighton, and Nottingham; and the highest rates in Derby, Blackburn, and Bolton. The greatest mortality from scarlet fever occurred in Norwich, Birkenhead, Huddersfield, Salford, Bristol, Blackburn, and Halifax; from "fever" in Manchester, Portsmouth, Salford, and Plymouth; from measles in Manchester, Bolton, and Derby; and from diarrhœa in Blackburn and Bolton. The 38 deaths from diphtheria in the twenty-eight towns included 25 in London, 2 in Birmingham, and 2 in Liverpool. Small-pox caused 13 deaths in Sheffield, but not one in Greater London or in any of the twenty-six other large towns. Only 4 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; whereas the number of cases of scarlet fever in the Metropolitan Asylums Board hospitals and in the London Fever Hospital had increased to 1759. The deaths referred to diseases of the respiratory organs in London, which had been 142, 160, and 219 in the preceding three weeks, declined again last week to 206, and were 51 below the corrected average. The causes of 72, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Hull, Brighton, and in five other smaller towns. The largest proportions of uncertified deaths were recorded in Newcastle-upon-Tyne, Oldham, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·3 and 17·7 per 1000 in the preceding two weeks, rose again to 18·1 in the week ending October 8th; this rate exceeded by 0·6 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 12·3 and 13·0 in Greenock and Perth, to 18·7 in Glasgow and 26·5 in Paisley. The 453 deaths in the eight towns last week showed an increase of 11 upon the number in the previous week, and included 22 which were referred to diarrhœa, 19 to scarlet fever, 17 to whooping-cough, 7 to diphtheria, 6 to "fever" (typhus, enteric, or simple), 3 to measles, and not one to small-pox; in all, 74 deaths resulted from these principal zymotic diseases, against numbers declining in the preceding four weeks from 112 to 71. These 74 deaths were equal to an annual rate of 3·0 per 1000, which exceeded by 0·3 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 55, 28, and 17 in the three previous weeks, rose again last week to 22, of which 8 occurred in Glasgow and 7 in Dundee. The deaths from scarlet fever, which had been 11 and 12 in the previous two weeks, further rose last week to 19, and included 7 in Dundee, 6 in Glasgow, 3 in Perth, and 2 in Edinburgh. The 17 fatal cases of whooping-cough showed a decline of 6 from the number in the preceding week; 6 occurred in Glasgow, 4 in Edinburgh, 2 in Leith, and 2 in Dundee. The 7 deaths from diphtheria showed a further slight increase upon recent weekly numbers, 5 occurring in Glasgow. The deaths referred to "fever," which had been 11 in each of the preceding three weeks, declined last week to 6, of which 3 occurred in Glasgow and 2 in Paisley. The deaths attributed to acute diseases of the respiratory organs in the eight towns, which had been 62 and 83 in the preceding two weeks, declined again last week to 78, and were 15 below the number returned in the corresponding week of last year. The causes of 56, or more than 12 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 34·3, 30·6, and 30·9 per 1000 in the preceding three weeks, declined to 24·2 in the week ending October 8th. During the thirteen weeks of last quarter the death-rate in the city averaged 31·0 per 1000, the mean rate during the same period being but 19·6 in London and 18·2 in Edinburgh. The 164 deaths in Dublin last week showed a decline of 45 from the number in the previous week; they included 13 which

Digitized by Google

were referred to diarrhœa, 6 to measles, 4 to "fever" (typhus, enteric, or simple), 3 to scarlet fever, 2 to whooping-cough, 1 to diphtheria, and not one to small-pox. Thus the deaths resulting from these principal zymotic diseases, which had declined in the preceding seven weeks from 78 to 37, further fell last week to 29; they were equal to an annual rate of 4·3 per 1000, the rate from the same diseases being but 1·9 in London and 2·2 in Edinburgh. The fatal cases of diarrhœa, which had ranged in the preceding seven weeks from 38 to 19, further fell last week to 13. The deaths from measles also showed a further decline from recent weekly numbers, while those referred to "fever" showed an increase. The fatal cases of scarlet fever, "fever," and whooping-cough did not show much variation from recent weekly numbers. The deaths of infants showed an increase of 1, while those of elderly persons were fewer by 9 than those returned in the previous week. Four inquest cases and 3 deaths from violence were registered; and 49, or nearly a third, of the deaths occurred in public institutions. The causes of 22, or more than 13 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

"THE PRESYSTOLIC MURMUR, FALSELY SO CALLED."

To the Editors of THE LANCET.

SIRS,—In a very interesting contribution to THE LANCET of Oct. 1st and 8th, Dr. Dickinson has once more raised a question as to the true character of the "presystolic," or, as I prefer to call it (and as it is usually called here), *auricular-systolic* murmur, as observed in cases of mitral stenosis. The controversy invited by Dr. Dickinson's communication is, as he himself admits, not a new one, inasmuch as it was exhaustively treated in your own columns in March and May, 1872, as between the late Dr. Andrew Barclay and others, Dr. George Balfour of Edinburgh being on that occasion, as in his well-known book published in 1876, the able and sufficient champion of the view which I regard as the correct one, and which has been taught in Scotland for thirty years or more to medical classes in Edinburgh and Glasgow. Still, there is an advantage in having any matter of medical doctrine supposed to be still in controversy taken up by one like Dr. Dickinson, who is too much in earnest, too practical in his tendencies, and too well versed in original research to be likely to trouble himself at all with a purely academical discussion *pro* or *con*. For this reason I venture to submit a brief rejoinder to his "remarks" in the same spirit as the remarks themselves. I do not propose fully to discuss the question of the auricular-systolic murmur on the present occasion, but only to indicate what I consider sufficient reasons for adhering to the customary nomenclature and views of its nature and causation.[1]

Perhaps it may be as well to place in the front of the argument the points on which both sides are agreed. Fortunately Dr. Dickinson is by no means grudging in his admissions in this respect, nor does he obscure the question at issue by any irrelevant or disturbing doubts in respect of the practical significance of the murmur as a diagnostic fact. After describing anew the murmur and briefly alluding to the theories of it, he adds (p. 650): "Some of these propositions I am about to dispute, but there is no possibility of doubting the practical outcome. The murmur which has been thus described ..... is pathognomonic of mitral stenosis. If the theory is to be judged only by the correctness of the diagnosis which follows from it, it must be correct." And, again, towards the close of his paper (p. 697): "It may be accepted as a general truth that a diseased mitral valve does not shut unless the orifice is narrowed; thus the so-called presystolic murmur becomes a sign of stenosis. For this great landmark of cardiac diagnosis we have to thank Dr. Gairdner. Our estimation of its value will not be lessened by any difference of opinion as to the precise origin of the morbid melody which we can so readily recognise, and from which we learn so much." Dr. Dickinson is here almost too generous; but the history of this subject is a long and involved story, which has been admirably told by Dr. Balfour in an address[2] recently published, and I therefore abstain from remarking upon it further than to indicate that no kind of personal question, apart from the purely scientific issues involved, interferes, or at least ought to interfere, in the argument on the present occasion.

We may take it, then, as admitted on all hands that a murmur immediately preceding the first sound, having, moreover, a peculiarity of character and intonation which Dr. Dickinson does not fail amply to recognise, and very frequently, if not invariably, accompanied by some alteration in quality of the first sound itself, as well as by a more or less pronounced reduplication of the second sound, is distinctive of mitral stenosis. The question at issue is whether the murmur so characterised is produced only while the ventricle is in systole (but at the very commencement of the systole) before the auriculo-ventricular valve has had time to become completely closed, or whether it occurs at the very end of the ventricular diastole, and while the auricle is contracting (the valve, of course, being still in the open position). It might even appear to some that this question is, after all, an academical rather than a practical one, or, as Dr. Balfour puts it, "To all such arguments it might at first sight be sufficient to reply that so long as what is called a presystolic murmur is duly recognised as an infallible sign of mitral stenosis, it is a matter of no importance whether we regard it as auricular-systolic or ventricular-systolic in rhythm."[3] But in a matter of this kind nothing that conduces to clearness of thought and accuracy of observation can be said to be of *no* importance. There are curiosities, even mysteries, enough about the murmur of mitral stenosis, clear as its practical significance may be in most instances, which should make us anxious to avoid all needless confusion of thought about it. Besides, I quite agree with Dr. Dickinson when he says that "a sum has been known to prove, notwithstanding that errors have crept into the working of it." I will only add, therefore, that in my own teaching, from first to last, the practical fact of the coincidence of the murmur with mitral stenosis has been set forth always as of the first, and the theory of it as of the second, degree of importance. But I am by no means disposed to concede that there is, as the matter stands at present, any doubt or insecurity in respect of the theory of this murmur as set forth by me in 1861. In point of fact, the theory stands, if it stands at all, by its own inherent simplicity as an explanation of the facts. If, as Dr. Dickinson affirms, "Dr. Gairdner's position became that of orthodox medicine," the "orthodoxy" is not the result of any highly elaborated arguments or unduly dogmatic declarations on my part, much less of any assumption of papal or ecclesiastical infallibility, for to "orthodoxy" of this kind I have ever been entirely opposed.

There is a feature of the auricular-systolic murmur (as I still venture to call it) which has been overlooked, or cast into the shade, by Dr. Dickinson, as well as by all his predecessors, in the views he has adopted, but which the reader will find most carefully and deliberately laid down, and illustrated by a diagram, in my first publication on the subject in 1861. "The auricular-systolic murmur may merely precede the first sound—i.e., it may follow the pause of the heart's action; or it may appear to be prolonged out of, or even quite through, the period of rest, being in this last case necessarily associated with a degree of the ventricular-diastolic murmur presently to be described. Its essential character, however, is preserved in every case, as above defined, and as represented in the diagram."[4]

In other words, while the most *characteristic* (and also the least variable) element in the A.S. murmur is that which immediately precedes the first sound, and coincides (as I believe) with the auricular systole, the murmur itself is often much more prolonged than this, and may cover not only the auricular-systolic period, but also the period corresponding with the active diastole of the ventricle, and also with the pause, or rest, of the heart; and in such cases

[1] I may refer the reader also to the *Glasgow Medical Journal* for Sept. 1887, p. 226, for some further observations on a paper by Dr. McVail, which, I observe, has been reproduced in the *British Medical Journal* of last week without my rejoinder as made in the Medico-Chirurgical Society immediately after the paper.

Digitized by Google

(I will add, as the result of all my subsequent experience) the murmur, though varying, it may be, in intensity, is usually homogeneous as to character and intonation,[5] so that even in cases of the most complex and combined murmurs it is for the most part easily distinguished from the others which may be accidentally associated with it.

Now, I fail to see how this fact (supposing it to be a fact) can be reconciled at all with Dr. Dickinson's hypothesis. On the view of the case that I have adopted, it is at least possible to understand how, with a stenosed orifice, there should be a murmur extending over the entire period when the ventricle may be supposed to be gradually filling, *a tergo*; although it may be, and is, difficult to explain why this murmur should vary so much in intensity, and otherwise, in individual cases of like pathological characters, and even in the same case at different times. But it is utterly out of the question to suppose that a murmur which begins soon after the second sound, and extends throughout the pause up to the first sound (with varying intensity, but essentially unchanged characters), can be associated with the ventricular systole or caused by regurgitation from the ventricle. The only explanation of such a phenomenon open to Dr. Dickinson would be to affirm in all such cases that the murmur heard was not *one* murmur, but *two*. And this I take to be his actual explanation, judging from the latter part of his paper (p. 695), in which he aims at rehabilitating the damaged credit of the old "mitral diastolic" murmur of Hope and others, by distinguishing it from the so-called presystolic. But he will excuse me if I prefer the evidence of my own ears, long exercised in this very inquiry, and assuring me on many occasions that the long-continued, rumbling, and very characteristic murmur to which I am now referring is identical, in all its essential attributes, with the much more brief murmur immediately preceding the first sound, to which we in Scotland usually apply the term auricular-systolic (A.S.).

Take, for example, the very remarkable, if not unique case recorded at pp. 602-3 of my "Clinical Medicine," a case all the more valuable for my present object, because the clinical description of it was written and published years before the verification of the essential diagnosis by a post-mortem examination. In that case there was, strictly speaking (as afterwards discovered), no stenosis at all; but there was, on the other hand, a ball-valve obstruction of the tricuspid orifice caused by a globular tumour depending from the auricle, and acting as a plug, partially damming up the opening, but *only* during the flow of blood from the auricle to the ventricle. The right ventricle and all the parts in front of the tricuspid valve were in this case absolutely normal; so that there was no excuse whatever for ever suspecting a murmur of regurgitation, or, indeed, any other murmur than one of obstruction.[6] These facts give to the following brief description an importance out of all proportion to the amount of detail in it, inasmuch as it was the carefully condensed result of a large number of observations made over a lengthened period of hospital residence on a case which, on account of its exceptional character, attracted much attention. "The cardiac murmur begins immediately after the second sound, continues (*diminuendo*) throughout the pause, and then goes on (*crescendo*) up to the first sound, at which it stops abruptly. I think tricuspid contraction [it should have been *obstruction*, to correspond with the actual conditions afterwards found] may in this case be predicated with all but mathematical certainty; the fact, however, of having witnessed this typical instance only serves to make me more entirely confident that I cannot have overlooked the fact in many other cases." It will be observed that the intonation and acoustic characters of the murmur are not here critically reported, but the impression intended obviously to be conveyed is of one and the same murmur, prolonged without a break through the entire interval. I am very sure, even now, that this *was* the impression vividly and instinctively conveyed to the ear throughout the long period of observation in this case. But if, as sometimes happens, the *diminuendo* portion of the murmur should have disappeared, or should become (according to Dr. Dickinson's apt poetic quotation) "a sound so fine that nothing lives 'twixt it and silence," there would be no small risk of misconception; the *one* murmur, homogeneous throughout, might then easily be conceived of as *two*, of which the former would be certainly diastolic in rhythm. This, at all events, is all that I can urge on behalf of Dr. Dickinson's descriptions to bring them into some kind of conformity with my own observations. And if this be not the authentic basis in observation for the "old mitral diastolic murmur," then I must simply affirm that I am not acquainted with it at all, and am therefore not in a position to recognise it as a separate and distinct phenomenon.[7]

There is another point in which Dr. Dickinson's descriptions fail to convey to my mind the impressions derived from the use of my own senses, and thus fixed in my mind as the result not of theory but of sheer experience. At page 651, col. 2, he speaks of the case, not at all one of infrequent occurrence, when a murmur preceding and a murmur following the first sound are associated together. He seems here to attribute to the advocates of the current theory a confusion of language or of thought, or both, on the strength of which he immediately builds up an apparent paradox in argument, such as he feels bound to repudiate. But the confusion and the paradox are alike foreign to all that I have observed and written upon the subject. When these two murmurs coexist (he says in effect) they are inseparably blended. "The two have become one. The presystolic and the systolic are so joined *that no man can put them asunder, or say where one begins and the other ends.*" I ask now, with some astonishment, Is Dr. Dickinson here professing to give his own observations or mine? If the latter, I would simply refer him to pp. 577-78 of my "Clinical Medicine," without quoting the passage at length, as it is somewhat long. He will there find that I have been at the utmost pains to show that these two murmurs are never thus inseparably blended; that they always preserve their exact separate rhythm, and are sharply demarcated from one another, either by the first sound remaining clear and definite (as it usually does) between the two, or by an abrupt change in the character of the murmur itself, marking, as it were, an interval between them (though the interval may be too brief to appear *soundless* to the listening ear). And this is not a mere matter of words or a trivial difference in respect of the facts; for it is on this very misconception that we are apparently to be driven into the false position that believing, as we do, these two murmurs to be absolutely distinct, we yet find them, as a matter of observation, thus inseparably blended. I say emphatically, for myself, that the error and confusion here, if any, are not mine. The two murmurs (A.S. and V.S., as we always denote them in Glasgow) both *are* and *appear* quite distinct to the ear in all but a fractional minority of cases. Nay, it is their very easy differentiation in fact that constitutes, in my mind, one of the leading objections to Dr. Dickinson's theory. For if *both* of these murmurs are in reality *ventricular-systolic*, and therefore murmurs always of regurgitation, why should they be ever distinguished, either in fact or in appearance, the one from the other? Dr. Dickinson's paradox thus, to my mind, proves fatal to his own hypothesis, and not to mine.

Since I began these hastily written remarks, which are all that I can ask you to give space for at present, I have received a letter from Dr. Sansom to the following effect:—"I am not at all convinced by Dr. Dickinson's reasoning in THE LANCET concerning the presystolic murmur—rather am I convinced the other way. I must meet his observation as to the *time* of the ventricular systole in a case of manifesting the murmur by a direct negative, for I have convinced

[5] In using this expression as that of the broad statement of the facts conveyed to my ear in most cases, I am not indisposed to admit, with Dr. Balfour, that the diastolic element of this murmur is softer, as a rule, than the presystolic; and that it may also occur in some cases when the latter is indistinct, or perhaps even absent. These cases are, however, so exceptional that I admit their existence with some difficulty, although they may possibly have been present to the minds of some of those great auscultators who have insisted upon the diastolic mitral murmur as "exceedingly rare"—"feeble, soft, &c., owing to the weakness of the diastolic current out of the auricle" (Hope); or who (like Walsh) have "never observed diastolic thrill at the left apex," and "have never heard this murmur of great intensity." See also a note further on upon this subject.

[6] The preparation illustrating this very rare case is now in my possession, and has been shown to numbers of persons, including a very full meeting of the Medical Section of the British Medical Association in London.

[7] I must, however, allow for a small and perplexing minority of cases in which, from one cause or another, the rhythm is difficult to follow, and even the facts remain more or less uncertain. I will not, therefore, declare absolutely against the old mitral diagnostic murmur; and I will observe a similar reserve as regards Dr. Austin Flint's curious but exceptional experience of a murmur, apparently of mitral stenosis, occurring with free aortic regurgitation and with an unindured mitral valve and orifice. (See the *Glasgow Medical Journal* for September, referred to above.)

Digitized by Google

myself and every observer in an instance now under my observation that the maximum of movement is exactly with the end of the murmur—i.e., with the ventricular systole." This, too, is entirely in harmony with such impressions as I have hitherto been able to form as regards the facts; but I should have hesitated in saying so in the face of the apparently precise statements and experiments detailed on p. 651 of Dr. Dickinson's paper, were it not that I very fully recognise the difficulty which Dr. Dickinson has himself experienced of making "two senses work together in exact consent." I will only say, therefore, that, so far as my observations go, Dr. Saneom is right; and from his well-known exactness and skill in the employment of mechanical appliances in cardiac diagnosis, I fully expect that he will be able ere long to supply further evidence upon the subject.

In the meantime I hope, and indeed feel sure, that Dr. Dickinson will excuse me for dealing thus imperfectly, on the spur of the moment, with his elaborate and very suggestive paper, and that he will also readily pardon any too eager expressions of dissent from his views, in the full conviction that such dissent is governed by, and indeed mainly due to, the sincere respect I have always entertained for his large and fruitful labours in various departments of scientific medicine.

I am, Sirs, yours truly,

W. T. GAIRDNER, M.D., LL.D., &c.,
Professor of Medicine in the University of Glasgow.

Glasgow, Oct. 11th, 1887.

To the Editors of THE LANCET.

SIRS,—It has a long time occurred to me to question the interpretation of murmurs generated at the various cardiac valves; and in relation to mitral disease, I have on more than one occasion in the out-patient room written down a diagnosis thus: Mitral systolic murmur—stenosis. I have also had prepared for some time the basis of a paper on this subject, but was diffident of publishing it, knowing how opposed the views contained therein would be to those generally accepted. Dr. Dickinson's brilliant paper in THE LANCET of Oct. 1st has shown me that, whilst differing from the opinion of most of the great authorities as to the cause of this so-called presystolic murmur, I am at least in good company when on the same side with Dr. Dickinson. Much therefore that I can say must be supplementary to, as well as in support of, Dr. Dickinson's contentions.

My basis of argument must, firstly, be made plain. I do not contend that a mitral stenosis is not often accompanied by a thrill and by a loud murmur terminating abruptly, which occupies the time in which one would suppose the ventricle to be in diastole, and which murmur we have been taught to call presystolic or "auricular systolic." But I do contend that this murmur is not generated at the mitral ring, but that it is generated by, and entirely owing to, altered flaps and chordæ tendineæ, and that it is evidence of regurgitation, and not of obstruction. In other words, although the so-called presystolic murmur may be, and probably is, diagnostic of mitral stenosis, the pathological condition which has caused this narrowing of the orifice has also, at the same time, caused thickening and rigidity of the mitral valve with thickening and shortening of the chordæ tendineæ attached thereto; and it is these latter conditions which form the musical instrument. The recognition of the murmur, like the writing on the wall, has been apparent; the interpretation thereof has not been so easy.

In my out-patient practice at the North London Hospital for Diseases of the Chest, I examined post mortem the hearts of two children who died after having had for some months all the physical signs of mitral stenosis. The dissections in both cases revealed stenosis, some little dilatation of the left auricle, together with the alteration in the mitral curtains, to which I have alluded. But (and here I would differ from Dr. Dickinson) the stenosis was not so marked a condition as the rigid thickened valve. The question then arose, How did, in each case, the miscalled presystolic murmur occur? There was in each case a prolonged first sound, with accompanying thrill. This first sound, which I looked upon as systole, was attended by, in fact replaced by, a murmur which increased in intensity towards the end of systole, till it finally terminated in a sharp note (or "snap" of Dr. Ormerod); then could be distinctly heard a break or interval, followed by a typical second sound. The sounds heard during this cycle of events may be represented by *f-r-u-u-m-p—dup*. Supposing this were tabulated so as to represent the views of our great authorities on valve disease, it might be written thus:—

	1.	2.
f r u Presystolic murmur.	*u m p* Systole.	*dup* Diastole.

But let us see how it would meet our views if written thus:

1.	2.
fru u mp Systole prolonged and laboured.	*dup* Diastole.

Against the first proposition I would contend that if the first part of the murmur be presystolic, there ought to be, as Dr. Dickinson insists, a break between auricular and ventricular systole; a period of slack water between the flow and ebb tide; an arrest between the up and the down stroke, as in fiddle-bowing,—a condition which does not occur. There must be invariably narrowing of the mitral ring with roughened surfaces of this ring and of the auricular aspect of the valve, there should be also auricular hypertrophy.

On the other hand, let it be conceded that a rigid flap hanging in the ventricle cavity, and attached to its wall by a shortened cord, responds slowly to the current raising it, and we have, as I think, all the elements producing the phenomena known as the presystolic murmur. The whole of the noise up to the "snap" is, I take it, caused by ventricular systole; it is synchronous with the heart's prolonged heave; the rigid mitral curtains which are edgeways on to the returning current vibrate by means of their rigidity being opposed to the current; regurgitation into the auricle is occurring all this time; the mitral flaps are being slowly raised (physiological time), they ultimately meet one another with a shock, systole is completed, and regurgitation arrested. I will compare this state of things to the lower lock gates of a canal when the lock is being filled. The current of the water is enough to gradually push the gates towards one another, some water at the same time escaping through them; the gates eventually close and fit tight with a sharp sound, and leakage is stayed. In a normal heart's action, I take it that the mitral flaps are raised at once directly the ventricular chamber begins to contract; the two flaps next meet one another, and their soft smooth convex surfaces come together with a slight noise. The right segment of the valve, being common to both aortic and mitral orifices, has a double function: it acts as a factor in completing the closure of the auricular-ventricular orifice, and it also serves as an inclined plane directing the column of blood into the aortic infundibulum. But in a rigid valve conditions are altered. There is no sudden closure by the mitral. The doors are heavy, they take some time to move, they are held down by thickened, altered, and inelastic cords; and when at last they do close, their meeting is marked by an abrupt, explosive sound, marking the climax to a murmur which has been going on all the while. The murmur may therefore be presystolic in the sense that the term systole, in view of its comparatively quick completion, is marked by the sudden closure of the valve, but it is still ventricular systolic in its causation.

As regards thrill. Must we be satisfied with the view that it is caused by blood being crowded through a narrow slit-like, roughened orifice; that a weak chamber acquires, in a short time, power enough to generate a vibration, which is coarse enough to be felt, but not rapid enough to cause a musical note? If this be so, should not the whole organ itself participate in the tremor, and therefore should it not be felt all over the cardiac area, although it might be intensified and accentuated at the mitral ring? This seems to me difficult to accept. Does it not seem more likely that a stiffened flap, held edgeways, or perhaps a little aslant, to the regurgitant stream shall fill all the conditions required to produce a thrill? A vocal cord produces a note; it also produces a thrill.

The proposition advanced in the foregoing may be summed up thus: In cases of so-called presystolic murmur there are—1. A thrill felt over the apex. 2. A prolonged roaring murmur, composed of distinct vibratory elements, terminating in a snap or bang. 3. There is no halt or break in rhythm, and no sudden alteration in musical character

Digitized by Google

between the commencement and the end of the murmur. 4. The roaring murmur is caused by the ventricular systole. 5. The termination thereof (or snap) represents the concussion of the mitral flaps and the arrest of regurgitation. 6. The thrill is produced by a rigid flap vibrating in a stream powerfully propelled.

Propositions 1, 2, and 3 may perhaps be granted. Propositions 4, 5, and 6 do not probably as yet meet the views of the profession; but, if I read Dr. Dickinson's paper aright, they are held by him as well as by myself.

I am, Sirs, yours obediently,

Seymour-street, W., Oct. 1887. SEYMOUR TAYLOR.

To the Editors of THE LANCET.

SIRS,—May I be allowed space in THE LANCET for a few sentences in defence of the auricular-contraction theory of the production of the presystolic murmur, which was assailed in last week's number by so great an authority as Dr. Dickinson, who contends that the murmur in question is really a regurgitant murmur of systolic rhythm?

With regard to actual points of observation, I am disposed to disagree with Dr. Dickinson only on one, albeit an important one. It is his statement that the presystolic murmur accompanies, and does not precede, the apex impulse. I have over and over again convinced myself, and others who were with me, that the presystolic murmur and its accompanying thrill do precede the impulse of the apex, and, moreover, close abruptly with it. Coming to matters of theory, a large class of cases of mitral stenosis which never present a presystolic murmur at all demonstrate the fact that the closure of the mitral valve takes place at the beginning of the systole, for in these cases both a systolic sound and a systolic murmur are present, but the sound invariably precedes the murmur. I quite agree with Dr. Dickinson that a mitral systolic murmur must be regurgitant. The preservation of the first sound in cases of mitral regurgitation, accompanied by a systolic murmur, is matter of common observation, not only in cases of regurgitation through a constricted orifice, but in cases where there is no disease of the valves, their incompetence depending on the muscle of the heart, as well as in cases of structural change in the valve curtains, while yet it is in an early stage, as witnessed in the course of acute rheumatism. Dr. Dickinson, in the following sentence seems to ignore altogether the large class of mitral regurgitant murmurs which are preceded by a first sound: "The ordinary or old-fashioned mitral regurgitant murmur simply takes the place of the whole first sound, and lasts to its end." In nearly all cases of mitral stenosis accompanied by presystolic murmur, a systolic murmur indicative of regurgitation through the deformed orifice may from time to time be heard; but this murmur invariably follows the first sound. Moreover, the *crescendo* character of the presystolic murmur and *diminuendo* character of the systolic murmur (usually soft and blowing in character) are well marked, and the two murmurs are separated by the first sound. The systolic is, no doubt, regurgitant, but it follows the first sound. The peculiar accentuated and shortened character of the first sound, I believe, depends on the small quantity of blood in the ventricle at the time of its contraction. The left ventricular walls are usually healthy, and contract with vigour, so to speak, on a light burden.

Dr. Dickinson refers to the difficulty met with in attempting to account for the absence of a pause between the presystolic murmur and an accompanying systolic murmur, but a first sound is always represented in these cases, and it is to it that the presystolic murmur "runs up." The sound implies only the closure of the valves, and the abrupt cessation of the current producing presystolic murmur is just the condition that explains the abrupt cessation of the murmur coincidently with the first sound.

Dr. Dickinson states that he has found that the presystolic murmur begins with systolic (i.e., ventricular?) movement, but such movement does not necessarily imply contraction. It seems very likely that there will be some movement communicated to the ventricles by the contraction of the auricles.

The difficulty of explaining the loudness and roughness of the presystolic murmur by a current of blood resulting from contraction of the thin-walled auricle is considered an objection to the auricular contraction theory, but a diastolic murmur due to mitral constriction sometimes possesses almost as much loudness and roughness as the presystolic murmur, and is quite commonly accompanied by marked thrill, yet the forces producing the soniferous current can only be the blood-pressure in the lungs and the sucking action of the expanding ventricle. The theory that explains the loudness and roughness of the presystolic murmur must also explain its remarkable limitation to the apex and its extraordinary capriciousness, as shown in its coming and going, while the structural conditions remain unaltered.

I am, Sirs, your obedient servant,

Manchester, Oct. 4th, 1887. GRAHAM STEELL.

To the Editors of THE LANCET.

SIRS,—Dr. Dickinson, in his excellent remarks on this subject, speaks of the hardihood of daring to take into question one of the accepted canons of cardiac medicine—viz., that promulgated by Dr. Gairdner. It will, I hope, be some satisfaction to Dr. Dickinson to know that I, for one, have never accepted this unphysical and unphysiological doctrine, but, on the contrary, have always taken the opportunity of exposing its fallacy to the members of my class.

The arguments which I have used to disprove an auricular systolic sound are precisely those employed with so much force by Dr. Dickinson—viz., first, that the auricular contraction is insufficient to produce the necessary vibration of the diseased valve; and secondly, and very obviously, there is no break in the so-called presystolic and systolic sounds.

It does not surprise me to find that such fancies as the one Dr. Dickinson combats should occasionally take the place of plain facts, when we find that there are a number of intelligent men who are unable to appreciate the simplest and efficient cause of the first sound of the heart. There are other *impenetrabilia* in our constitution, I fear, besides "colour blindness." I am, Sirs, yours truly,

Stratford-place, W., Sept. 30th, 1887. JOHN HARLEY.

GOUTY DIABETES.

To the Editors of THE LANCET.

SIRS,—Will you allow me to call attention to a class of cases which is not only a large one, but the cause of much anxiety and frequently of considerable disappointment to practitioners who have not had the opportunity of studying it on a sufficiently extensive scale and in detail. I allude to that variety of suppressed—or, more accurately, *undeveloped*—gout, in which the symptoms are chiefly and often characteristically "diabetic." Persons affected with this malady are generally of large frame, with little stability or power, full-sized but flabby muscles, and a tendency to the accumulation of fat. They are great—or intermittingly great—eaters, and energetic or impulsive, but weak and easily exhausted. The skin is pale, and they suffer from coldness of the extremities. They sleep badly at night, and worry in their wakefulness; while by day they are drowsy, and when falling asleep breathe heavily, or, if not roused, sink into a state verging on coma with puffing, sighing, or laboured respiration. They are commonly subject to attacks of vertigo, in which surrounding objects seem to race from left to right; and not seldom they have weak hearts with rhythmically irregular pulses, and perhaps a short mitral systolic murmur, which is not constant, but more likely to be heard when the heart is acting languidly than when it has been recently stimulated by exercise. The characteristic phenomena are: (1) very great variability in the quantity, colour, and density of the urine passed in twenty-four hours, and the want of relation between the bulk of the fluid consumed and that excreted; (2) sugar is present when the urine is small in quantity, rather than when it is abundant; (3) the acidity is abnormally low in proportion to the percentage of urea; (4) there is generally much uric acid (Haycraft's test) when the sugar is absent, and less than the average proportion of health when sugar is present; (5) albumen is often found soon after a meal, either with the sugar or during a free elimination of uric acid, and when there is no albumen the phosphates are generally in excess; (6) the liver is enlarged *vertically*, and the bowels are constipated, with occasional attacks of diarrhœa, the stools being pale when scanty, and bilious when profuse. Hæmorrhoids are usually present and troublesome in these cases, and when they do not bleed they

Digitized by Google

often attain great size. Not infrequently there is also a prostatic gleet.

I will not trouble you with any attempt to account for this curious and, as it may appear, contradictory combination of symptoms and indications, although I have my own theory, and may hereafter have something to say on the subject; nor will I venture to set out the *rationale* of the line of treatment which has proved serviceable. Suffice it to state the clinical facts as I have myself observed them, and to report the means by which the symptoms have been generally ameliorated—often, as it would seem, wholly removed. In the management of cases of this class many difficulties have to be encountered, and they are far from easy to overcome. Meanwhile, one thing is certain—namely, that dieted as it is the fashion to diet patients suffering either from gout or diabetes, and treated on conventional principles either at home or at the continental spas, the subjects of gouty diabetes do not do well. They may be for the moment relieved, but they quickly relapse and, on the whole, go from bad to worse steadily. It is with a view to plead for a more generous regimen and tonic treatment I am writing. Wisely, but liberally fed, with meat in such quantities as the stomach will take, *ordinary* bread and vegetables,—in short, a full mixed diet—dry champagne, which contains a minimum of alcohol and a large proportion of ether, and well-matured port wine, in appropriate and measured quantities (the effect being carefully watched), they do well. The albumen and sugar disappear; the quantity of urine excreted becomes normal and relatively regular. The pulse gains strength and rhythm, and the condition throughout improves, under some modification of the following treatment: Ferri lactatis, 10 gr.; acidi lactici, 15 m.; quiniæ puræ, 1 gr.; extracti convallariæ fluidi (*e floribus*), 10 m.; aquæ ad ½ oz.; every sixth hour, or in bad cases every fourth, or even third, hour. Should there be constipation, I add five or ten minims of the fluid extract of cascara sagrada (U.S.); or diarrhœa, or excessive diaphoresis, ten minims of tincturæ cotonis. The results of this management, in a considerable number of cases which have recently fallen under my observation, have been so good that I think it right to place the facts on record without further remark.

I am, Sirs, yours faithfully,

Hanover-square, Oct. 1887. J. MORTIMER GRANVILLE.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASE.

To the Editors of THE LANCET.

SIRS,—Dr. J. H. Walters undertakes, in your last issue, to prove that, as regards the town of Reading, compulsory notification has been shown by six years' experience to be valuable as against disease and also acceptable to the profession. I should like him to support this opinion by categorical answers to the following questions:—

1. In what respect and to what exact extent, as shown by the death-rate of, say, the last two years, has Reading benefited in health by the system? I do not want statistics of notifications, but of deaths.

2. Is the form of notification such as to permit the practitioner, as he may in Edinburgh or elsewhere, to exclude the health officers from the disinfection and sanitation of the infected house if it is his interest to do so?

3. What proportion of the deaths are recorded by the burial authorities as having been attended by chemists and other unqualified practitioners?

I put these questions because I have in vain asked for evidence, presented by death-rates, that notification towns have improved in health in any greater degree than non-notification towns similarly situated; because I have reason to know that in towns in which the medical attendant is allowed (by stating in the notification form that the interference of the health officers is not necessary) to keep those officers from interfering with his private cases, the notification is a complete sham, many of the cases notified and paid for not being infective at all, and many infective cases being allowed to fructify just as if their existence had never been notified.

Finally, I have reason to believe that, if inquiry were made as to the number of persons attended by quacks, chemists, and other unqualified persons in notification towns, it would be found that the dread of the interference of the health officers drives very many of the sick into the nets of these persons. Can anyone produce actual figures to disprove these statements? If not, no one should trust in the unsubstantiated imaginings of Lord Basing or any other pro-compulsion partisan.—I am, Sirs, yours &c.,

Dublin, Oct. 8th, 1887. ARCHIBALD H. JACOB, M.D. Dub.

EMPYEMA FOLLOWED BY MELANCHOLIA.

To the Editors of THE LANCET.

SIRS,—I have been greatly interested by the account of Dr. Squire's case at the North London Hospital for Consumption, recorded in THE LANCET of Sept. 17th, and I am tempted to give you the notes of a somewhat similar case of my own, the curious point being that the mental symptoms in my case occurred within a few days of Dr. Squire's patient becoming melancholic.

W. B——, aged sixty-five, was taken ill about Christmas, 1886. Pleurisy was diagnosed early, but was almost devoid of pain. The left side was involved. Hiccough became incessant about the beginning of February, when my partner (Mr. G. H. Jackson) was called in. On Feb. 14th the patient was aspirated and nearly six pints of pus were removed. On the 17th I saw him with Mr. Jackson. The temperature had only once reached 99·8°, and that was quite early in the case; it was then 98·4°; respiration 24; pulse varied, about 90. The heart was displaced a little to the right. The dulness extended downwards to a distance difficult to ascertain, but the thoracic cavity gave very little evidence of fluid or consolidation. He lay on the left side. On the 19th Mr. J. Hutchinson saw him and agreed in employing free drainage, but advised us not to excise any bone, as he considered the space between the ribs sufficient. On the 20th I incised the seventh space in the anterior axillary line and inserted a very large drainage tube. A lead probe passed nearly up to the clavicle and in all directions freely. About a quart of pus was removed. Temperature 98·8°; respiration 22; pulse 96. The operation was performed under chloroform, but only lasted a few minutes. Next day his pulse intermitted every third beat with perfect regularity. The apex beat was now one inch to the inner side of the nipple. On the 27th delusions were noticed, and his mental condition grew worse daily up to March 20th, when improvement began to be seen. During this time the wound had gone on perfectly well, and as there was very little discharge the tube was removed on March 8th, in the hope that if by chance the chest closed the general health would improve. On the 14th the temperature rose to 99°, and the pulse was 103 and rather weak; the wound had closed. On April 4th the old wound burst open and a large quantity of pus escaped, and for a week the amount of discharge was great. The refilling had been watched with anxiety, but the choice lay between leaving nature to find a vent, or risking a recurrence of the insanity from which he had now so nearly recovered. About April 14th the discharge had abated materially, but I kept the tube in till May 7th, when, on its removal, the wound closed at once. His mind had now perfectly recovered, and on June 24th his only complaint was a dragging sensation on the left side. Practically nine weeks elapsed between the operation and complete closure.

I consider that the age should be noticed as an encouragement in similar cases. The melancholia assumed at one time a very dangerous type, but the watchfulness of his attendants avoided any disaster such as occurred in Dr. Squire's case, though a similar attempt was made. Did the melancholia result from weakness? Sir James Paget speaks of insanity after operations, and Dr. Savage has, I believe, recently made some remarks as to insanity in women after chloroform or other anæsthetics. I have attempted to glean information on this subject, but in vain, and I should very much like to hear from anyone who has met with a case of insanity after operation, as I propose to collect all the cases I can with a view to comparison. I wish to mention that agraphia was very much marked, and his penmanship improved *pari passu* with his general health. As a rule, the temperature was subnormal. He was not kept in bed a day longer than was absolutely essential, being out of bed thirteen days after the operation.

I happen to have seen Mr. B—— to-day (Sept. 30th). He tells me he is remarkably well, and weighs only 2 lb. less than the greatest weight he ever remembered scaling.

I am, Sirs, yours faithfully,

Tottenham, Sept. 30th, 1887. A. OGIER WARD, M.D.

"THE TREATMENT OF SCARLET FEVER."

To the Editors of THE LANCET.

SIRS,—Mr. Arthur Wiglesworth, in his letter to THE LANCET of October 8th, draws attention to the treatment of scarlet fever by the internal administration of carbolic acid. I have recently had two cases of this disease under my care, one of a very severe character, in which this method of treatment was resorted to, and with a satisfactory result. Dr. Alexander Keith of Normanby, in a communication to THE LANCET of Jan. 22nd, 1869, calls attention to the treatment of these zymotic diseases by the internal administration of carbolic acid. Six hundred cases were so treated, with five deaths. The dose of pure carbolic acid administered was from about four to six minims. He believes that the physiological effects of the acid are profuse perspiration, rapid lowering of the pulse, subsidence of pyrexia, cleansing of the tongue, diminution of soreness of throat, and increase of appetite; he also observed, as noticed by Mr. Wiglesworth, that the urine was of a dark colour.

I am, Sirs, yours faithfully,

Barking, Oct. 8th, 1887. SAMUEL LEE.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

NEWCASTLE.

THE relations of the College of Medicine with it students are at present rather strained. This unpleasant state of affairs has arisen out of the students' boisterous behaviour at the opening on the 4th ult. It is true that the students have become more and more unruly on these occasions the last few years; but on the last occasion a speaker unfortunately lost his temper and made use of a rather strong expression to the students; this gave rise to a scene which may be described as little short of a riot. For the maintenance of order the College authorities have taken the extreme steps of expelling three students, and have suspended nine others for a period of six months. Although some of the students have misbehaved, the punishment is considered to be rather Draconian, and the case might still be met by an apology and a reprimand. It is felt that, although the students have fallen under censure, the authorities are not altogether free from blame.

GATESHEAD CHILDREN'S HOSPITAL.

The committee of the Gateshead Children's Hospital, having been disappointed in obtaining the site originally selected, have been presented with a very eligible one by Lord Northbourne and a donation of £200. This gift makes £900 contributed by the Northbourne family.

SUNDERLAND.

In his quarterly report, Mr. A. E. Harris, the medical officer of health, points out that the death-rate, 19·35 per 1000, is the lowest since his appointment in 1873. The report refers to the use of feeding bottles as the cause of many deaths of children who died under twelve months. Fourteen were suckled, fifty-three fed by the bottle, and three otherwise fed. Mr. Harris states as his opinion that the use of the feeding bottle is often resorted to from laziness, and to his mind feeding with the spoon is perhaps the best form where the infant has to be fed.

RIPON.

A very painful sensation was caused in the neighbourhood of Ripon last week by the death of Mr. Thomas Millar, surgeon, of Kirby Malzeard, near that city, who died in consequence of a carriage accident. Mr. Millar was thrown from his gig on Monday morning. He was being driven by a boy, and the horse becoming restive the whip was used, the result being that the animal reared and both the occupants were thrown from the trap. The boy did not receive much injury, but Mr. Millar died from his injuries on the following Friday.

Newcastle-on-Tyne, Oct. 10th.

THE foundation stones of the extension of the Providence Eye Hospital at St. Helens were laid on the 6th inst. by Lord and Lady Stanley.

EDINBURGH.

(*From our own Correspondent.*)

THE DISCUSSION ON SCARLATINA.

LAST Wednesday the adjourned meeting of the Medico-Chirurgical Society for discussing the subject of Scarlatina was held in the hall of the Society for Promoting the University Education of Women. There was a considerable attendance of members and visitors; but it is to be regretted that many leading Edinburgh physicians and teachers of the school were unable to be present and take part, as it was hoped they would do. The first business of the evening was the reading of a further *interim* report by the committee appointed to inquire into recent researches into the etiology of the disease. The conclusion of chief importance at which they have arrived so far is to the effect that one of the microbes described by Mr. Edington as a harmless organism is identical with that recognised by Klein as the streptococcus scarlatinæ. In commenting on this conclusion from the president's chair, Professor Grainger Stewart, who is convener of the committee of inquiry, drew special attention to the important issue which it raises in relation to Dr. Klein's researches, for with this organism it appears Mr. Edington had already experimented on the human subject with negative results. In other respects the report was of little interest, save that the experiments performed by the committee seem to have produced no positive evidence in favour of the pathogenic action of the bacillus, while they are too scanty for the aggregate negative results obtained to increase materially the doubt which attaches to its true significance in relation to the disease. The discussion which ensued dealt chiefly with the treatment of the disease and with methods of prophylaxis. Under the former heading, the chief controversy was in regard to the best method of combating pyrexia in the acute stage, and of treating the renal, glandular, and articular after effects of the disease. In regard to the second point, Dr. Ritchie spoke of the value of sulpho-carbolate af soda in small doses, along with isolation, as a prophylactic measure; Dr. Illingworth referred to his encouraging experience with biniodide of mercury; and Dr. Jamieson referred to the method of inunction with antiseptics and antiseptic warm baths. Drs. P. A. Young, Buist, and Murdock Brown also took part in the discussion, which was summed up in a few words by the President, who thought it had been of value in many practical directions, although it had shown how great a need there was for further light upon all aspects of the question. At a private business meeting held subsequently, the Committee of Inquiry were authorised to continue their research.

THE POST-GRADUATE COURSE.

The Autumn Session, if one may so designate what has now become a regular part of the year's teaching work in Edinburgh, comes to an end at the close of this week. The satisfactory results of this year's course, both as regards the interests of teachers and taught, render the maintenance of the system a certainty, and reflect considerable credit on the men to whose foresight and energy the orginiation of the system is due. It is fifteen months since, after some preliminary conferences with his colleagues in the University and the Extra-academical School, Professor John Chiene drew public attention to the project in his address to the Edinburgh graduates on the 2nd of August, 1886. In the course of that address he pictured to his hearers the continuity of personal intercourse which could thus be maintained between themselves and their *alma mater*: showing that the benefit to be derived from the system was a mutual advantage, giving to the school a new and larger interest in preparing to supply its past graduates with practical instruction on an advanced basis, while they, in their turn, profited no less by coming in contact with the practical demonstration of recent advances, than by renewed intercourse with the minds to whose activity many of these are due. The astonishing success of the first effort made in Edinburgh last year has not been without distant as well as local effects: the latter seen in the permanent system already referred to, that has taken root in Edinburgh; the former evidenced by the springing up of similar systems in other centres of medical education. Birmingham was the first to

Digitized by Google

follow the lead, a short course of lectures to graduates having been held there last November. This year Aberdeen has already seen the satisfactory completion of a holiday course for graduates; while reports from Charing Cross show that the system can thrive in the metropolis no less admirably than elsewhere. Although the course in Edinburgh this year has shown a great development as compared with last year's course, it is evident, from the expressed desires of those attending the demonstrations, that there must be a still greater differentiation in next year's curriculum if the wants of all are to be supplied. This can be accomplished without difficulty, since the number of teachers in Edinburgh is so considerable. By working on the basis of cordial co-operation that has so far obtained, a suitable division of labour among them may be established, which will include the practical treatment of all such subjects as are susceptible of tutorial demonstration.

AN AGED ZOOLOGICAL SPECIMEN.

Many old Edinburgh students and others acquainted with the Royal Botanical Gardens will hear with regret of the death of the famous sea anemone that has been kept there for so many years. Its great age—for it survived until the sixtieth year of its captivity—and the immense number of its immediate offspring, amounting to over 600, had obtained for it the familiar cognomen of "granny." It was a specimen of the Actinia mesembryanthemum, found at North Berwick in 1828 by Sir John Dalyell, in whose house it remained until the time of his death. It then came into the possession of Professor Flemming, D.D., and has since been cared for by three successive curators of the Royal Botanical Gardens. Its portrait appears in an elaborate monograph by P. H. Gosse on the Actiniæ, and it is also figured in Sir J. Dalyell's publication on the "Rare and Remarkable Animals of Scotland." So great was the public interest in this long-lived zoophyte, that an album was kept for many years in which were inscribed the names of its particular visitors; this volume contains over 1000 autographs, among them those of many distinguished travellers and scientific men. This interesting creature was fed regularly once a fortnight with half a mussel, and was supplied with fresh water after each of these meals. It was apparently in robust health until a few weeks ago, when it was attacked with a parasitic disease (*saprolegnia*), to which it shortly succumbed.

Edinburgh, Oct. 11th.

DUBLIN.

(*From our own Correspondent.*)

ROYAL UNIVERSITY OF IRELAND.

A MEETING of Convocation was held last week, presided over by Lord Emly, Vice-Chancellor of the University. After some preliminary business had been transacted, the adoption was moved of an additional report of the annual committee, read at a meeting held last December. It had reference to matters that arose with regard to a rule adopted by the Senate, providing that the signature of each person applying for admission as a member of Convocation should be his own. In consequence of some matters brought before the Annual Committee by the secretaries, the opinion of the Attorney-General was taken on the matter. It appeared that some seventy or eighty applications had been put in, all apparently in the same handwriting. A difficulty then arose with the secretaries as to the registration of the names, and in the result the opinion of the Attorney-General was taken, which stated that there was no means of testing the genuineness of the signature, and therefore the validity of the application, and suggested that the matter should be brought before Convocation. The resolution having been passed, Dr. Thomson proposed the adoption of the report of the Annual Committee. The committee submitted the following resolutions:—(1) That the Standing Orders 50 to 55, which were rescinded at the last meeting of Convocation, be restored. (2) That, pursuant to the said orders, an annual committee for the ensuing year be now elected. (3) That the following new Standing Orders be adopted: "That in future no alteration of the Standing Orders be made at any meeting of Convocation except at the ordinary annual meeting of Convocation, nor unless notice thereof shall have been given at the next previous meeting of Convocation." The report having been seconded, was agreed to. Professor Pye proposed a resolution in reference to the extent of study to be pursued by candidates for medical degrees in the University. He thought the regulations did not provide sufficient protection to the public, inasmuch as they permitted students obtaining degrees in medicine, surgery, and obstetrics, and a diploma in sanitary science, after a professional training of three years. The Vice-Chancellor having pointed out that this was one of the matters under the consideration of the medical committee, Professor Pye withdrew his resolution. The Annual Committee was elected. The last business before the meeting was a series of resolutions by Mr. Croke, but a quorum not being present no action was taken in the matter, and the proceedings terminated.

THE DEATH-RATE OF DUBLIN.

At a recent meeting of the Dublin Sanitary Association attention was directed to the Registrar-General's returns, and to the great increase in the Dublin death-rate. The general death-rate in Dublin during the quarter ending October 1st was 30·9, as compared with an average rate of 28·1 during the corresponding quarter of the previous five years, and with a rate of 19·6 in London during the corresponding quarter. The fatality from zymotic diseases has largely increased, the deaths by this class of affections rising from 212 in the first quarter of the present year to 365 in the second and 776 in the third quarter. In the entire year 1886 the total deaths from zymotic diseases amounted to 1100, while for the nine months of the present year they numbered 1353.

At a meeting of the Public Health Committee of the Corporation on Tuesday, a report was read from Sir Charles Cameron, medical superintendent officer of health, on the subject of the abnormally high death-rate in certain districts in the city. In this he states that the severity of the measles epidemic depends to some extent upon the number of children who had not been attacked in previous years. In 1886 there were only nine fatal cases of measles, and consequently but comparatively few of the many children born during that year could have been protected from measles by having had a slight attack of the disease. Similarly, in 1884, there were but 21 fatal cases recorded in Dublin, and in the year following the mortality rose to 250. The high mortality has also been largely influenced by other indirect causes, such as exposure to cold, want of proper food and care. Two important factors in the recent high death-rate have been diarrhœa and dysentery. These Sir C. Cameron attributes to the excessively high temperature during the summer and autumn, and to the extreme dryness of the atmosphere. The intense heat favoured the more rapid decomposition of organic matters, rendering the air more impure, and causing certain food to undergo putrefactive changes more readily. In conclusion, he points out that the death-rate in Dublin from preventible diseases has undergone a marked decline in the last five years, and that two of the diseases which are largely prevalent in towns in an insanitary condition have almost disappeared from Dublin—viz., typhus and enteric fevers.

The Introductory Lecture at the opening of the Medical School of the Royal College of Surgeons will be given this year by Sir W. Stokes, Professor of Surgery at the College.

Dublin, Oct. 12th, 1887.

PARIS.

(*From our Paris Correspondent.*)

PROF. VERNEUIL ON IMAGINARY LINGUAL ULCERATION.

AT the meeting of the Academy of Medicine last week, Professor Verneuil read a note on an affection to which he gave the name of "imaginary ulceration of the tongue," characterised by intense local pain, without, however, any appreciable lesion. He looked upon it as a purely neuralgic affection of the tongue, and compared it to an affection of the breast described by Velpeau under the name of imaginary tumour of the breast, which, like the above-named affection, was also characterised by intense local pain without any appreciable lesion. In both cases the mind is very much affected, and the patients almost invariably suppose that their malady is of a cancerous nature.

Digitized by Google

The treatment adopted by Professor Verneuil was that he employed in neuralgia in other parts of the body, in which he was always successful. He stated, however, that in case of failure he would not hesitate to employ hypodermic injections of analgesic substances, cauterisation with the thermo-cautery of the painful part, and the destruction of the calciform papillæ which are generally to be found on the tongue in such cases. As for neurotomy, he would discard it, not only on account of the difficulty attending such an operation, but owing to its being impossible to know whether it is the lingual or the glosso-pharyngeal nerve that should be operated on. A long discussion followed, when most of the speakers agreed with Professor Verneuil as to the nature of the malady, but added that according to their experience the subjects were generally monomaniacs, and should be treated as such.

FLUORHYDRIC ACID IN CONSUMPTION.

Dr. Garcin, physician to one of the dispensaries established in Paris for the succour of patients applying for aid during the night, recently made a communication to the Academy of Sciences on the treatment of pulmonary phthisis by inhalations of the fumes of fluorhydric acid mixed with air, which he has found most efficacious in this affection. From the month of August to within a week ago he had observed 100 cases of pulmonary phthisis in different stages. The results obtained were the following; Stationary condition, 14; improvement, 41; cures, 35: deaths, 10. The procedure employed consisted in ordering the patient to remain for an hour daily in a room measuring six cubic metres of air saturated with fluorhydric acid. This saturation is obtained by passing a current of air by the aid of a pump into a jar of gutta-percha containing of distilled water 300 grammes, fluorhydric acid 100 grammes. Under the influence of this medication, the fits of coughing are at first rapidly diminished, and then cease altogether. The sputa are changed in character, the dyspnœa and the spots of pleurodynia are also diminished. By this treatment the bacilli disappear in a few days, and at the end of fifteen or twenty sittings the condition of the patient is considerably improved, if not cured. To obtain local anæsthesia in an operation for in-growing of the nail, the toe is sprayed with ether. Dr. Chandelux of Lyons observes that it takes some time before the analgesic effect is obtained, and in order to favour the production of this latter the author employed Esmarch's bandage, of course previously applied to the limb to be operated on. In using this expedient, Dr. Chandelux found that anæsthesia was obtained in from twenty to forty seconds; whereas by the spray, without the previous application of the bandage, it requires on an average two minutes. After the employment of the ether spray, and when once the part becomes cold, the anæsthesia lasts about three minutes longer, thanks to the ischæmia produced by the application of Esmarch's bandage, owing to the heat conveyed to the part through the blood being suppressed. The preceding method has also the advantage of preventing the flow of blood during the operation with the knife, so that the surgeon is thus enabled to minutely dissect the parts, and, in the case of the in-growing of the nail, no portion of the matrix of the nail is left in the half which is removed.

COMPARATIVE DEATH STATISTICS

A very interesting return has been prepared at the Bureau of Statistics attached to the Prefecture of the Seine, showing the relative proportion of deaths from fever and other diseases in different parts of Europe. With regard to typhoid fever, Besançon heads the list with 205 deaths per 100,000 of the population. Toulouse and Marseilles come next with 118 and 108 respectively. Paris has only 46, Brussels 29, and London 17. The lowest death-rates are at Leipzig and Vienna, which give 11 each. England generally compares favourably with France, Liverpool having 34 cases and Manchester 33. Marseilles appears to have suffered greatly from small-pox, the number of deaths from this disease being 578 per 100,000 of the population. As regards scarlet fever, Holland heads the list with 285, St. Petersburg 93, Glasgow 68, Brooklyn 51, Liverpool 47, Paris 18, London 17, and Rome only 5. The greatest mortality from consumption is in the large Austrian cities, and the smallest, contrary to general opinion, in English cities.

THE CLUNY NORMAL SCHOOL.

Shortly before the holidays a few cases of typhoid fever broke out among the pupils of the Cluny Normal School, when the whole of them were hastily sent home. This precaution was, however, considered to have come too late, as numbers of the youths carried away the germs of the disease; 150 were stricken down, and several died. An investigation showed that a main sewer and three feeders running through the foundations of the school buildings were obstructed, and the foul matter had permeated the soil around them. Moreover, it was found that the water used for drinking purposes in the school came from a well fed from a neighbouring spring. An analysis of this well water showed unmistakably the presence of the bacilli of typhoid fever.

DEATH OF M. RUOLZ.

M. Ruolz, the inventor of the electro-plate process which bears his name, has just died at Neuilly, at the age of eighty years. It was not generally known that he was a Doctor of Medicine. He was also *Docteur ès Sciences* and *Docteur en droit*. He never practised medicine. He began life by composing music: he then directed his attention to industry, and made some remarkable discoveries, and among them he devised the means for melting steel and utilising bronze for different purposes.

Paris, Oct. 11th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a Quarterly Meeting of the Council, held on Thursday, October 13th, the Minutes of the last meeting were read and confirmed.

Sir James A. Hanbury, K.C.B., was introduced and admitted a Fellow of the College.

A resolution was unanimously carried recording the regret of the Council at the decease of Mr. Richard Quain, past President and member of Council, and member of the Court of Examiners of the College; and their appreciation of the great services which he rendered to the College whilst holding those offices. A portrait of Mr. Richard Quain, by Richmond, bequeathed "to the Treasurer of the College of Surgeons, for such College," was accepted by the Council.

The following gentlemen, having been nominated by the committee, were elected examiners in Public Health, subject to the approval of the Royal College of Physicians:—Dr. T. Stevenson, Dr. Edward Ballard, Dr. Thorne Thorne, and Dr. W. H. Corfield.

Mr. John Marshall was re-elected a member of the Committee of Management.

The draft of the report to be presented to the Fellows and Members of the College at the meeting to be held on Thursday, the 3rd of November next, was approved and adopted. This can be had on application to the Secretary on and after Monday next.

The President reported that, in pursuance of the provisions of the Bradshawe Bequest, he had "chosen" Sir Joseph Lister, Bart., as the Bradshawe Lecturer for the present year, the lecture to be delivered at some convenient date in December. He further reported that Sir James Paget, Bart., will deliver the Morton Lecture on Cancer and Cancerous Diseases at a convenient date in November.

The Secretary submitted to the Council a copy of the conviction and sentence to two years' imprisonment at the Central Criminal Court of Mr. James McCully for libel. This being a criminal offence within the meaning of Clause 3, Section 16, of the Bye-laws, Mr. James McCully was removed from being a member of the College, subject to confirmation at the next meeting.

The motion of Mr. Hutchinson (see Minutes of Aug. 4th) was not brought forward, he being absent.

THE SERVICES.

ADMIRALTY.—The following appointments have been made:—Surgeon Ludlow T. Colthurst, to the *Scout;* and Surgeon John S. Lambert, to the *Royal Adelaide.*

ARTILLERY VOLUNTEERS.—1st Gloucestershire: Honorary Assistant Surgeon S. Skinner to be appointed Acting Surgeon (dated Oct. 8th, 1887).

RIFLE VOLUNTEERS.—4th Volunteer Battalion, the Gordon Highlanders: Acting Surgeon J. W. Mackenzie Gunn, M.B., resigns his appointment (dated Oct. 8th, 1887).—5th Cheshire: John Herbert Hacking, Gent., to be Acting Surgeon (dated Oct. 8th, 1887).—4th Volunteer Battalion, the South Wales Borderers: Frederick Erskine Paton, M.B., to be Acting Surgeon (dated Oct. 8th, 1887).

Obituary.

SURGEON-MAJOR G. C. ROY, M.D., F.R.C.S. ENG., INDIAN MEDICAL DEPARTMENT.

GOPAL CHUNDER ROY, son of the late Babu Loke Nath Roy, was born in Calcutta on May 16th, 1844. Having received his preliminary education in the Hindu School, he prosecuted his medical studies at the Calcutta Medical College and Hospital. During his college career he obtained prizes and certificates for proficiency in chemistry, medicine, surgery, and anatomy, and held the senior scholarship for two years. Passing out of the College in 1865, he obtained the diploma of L.M.S. His first appointment was as house surgeon to the first surgeon's ward, Medical College Hospital, under Dr. Fayrer. At this time he was also teacher of the vernacular class in the College. On expiry of the term of office he was recommended by his immediate superiors for the post of teacher of Nagpore Medical School. This appointment he held for two years, when, desirous of entering the Indian Medical Service, he proceeded to Europe in 1869. He obtained the F.R.C.S. Eng. by examination in 1870, and the degree of M.D. Glasg. in 1871. Dr. Roy stood sixth in the list of forty successful candidates. After finishing the Netley course, where he maintained his position, he returned to India towards the end of 1872, and was then appointed inspecting medical officer in the Burdwan district during the notorious epidemic fever which prevailed in that district for years. It was at this time Dr. Roy received the special thanks of the Government of India for the eminently satisfactory way in which he had discharged his arduous duties. Dr. Roy then successively held the appointments of superintendent of prison camp at Debri, civil surgeoncy of Serampore, superintendent of vaccination, Ranchi circle, and the civil surgeoncy of the latter place for a time, in addition to his other duties. In 1878 Dr. Roy was appointed permanent civil surgeon of Beerbhoom, which appointment he held up to the date of his death.

DR. GAETANO PINI.

DEATH has indeed been busy in the ranks of our Italian brethren, and the year now drawing to its close will be sadly memorable for the multitude of distinguished and promising practitioners it has seen cut down throughout the peninsula. The latest removal from the roll was in some respects the most difficult to replace.

Gaetano Pini was born on April 1st, 1846, at Leghorn, and pursued his preparatory studies in literature under the celebrated Latinist and man of letters, Atto Vannucci of Prato. From that provincial collegio he proceeded to Pisa, where he devoted himself to medical science, and after an interval similarly employed at the University of Naples he returned to Pisa, and graduated there in medicine and surgery, *summâ cum laude*, in 1869. The honours he took were all the more creditable when the interruptions to his curriculum are considered. In 1866, when Venetia had to be wrested from Austria, he enrolled in the 2nd Regiment of Grenadiers and bore an honourable part in the disastrous day of Custoza. Again, in 1867, when Garibaldi sought to force the surrender of the Papal States to Italy, young Pini, with a few Livornese and Pisan friends, joined the auxiliary column of Niccola Guerrazzi, and engaged in much active guerilla work in the Agro Romano, including some sharp encounters with the Pontifical Zouaves at Farnese, at San Lorenzino, and at Viterbo. With the solution of the Roman question, brought about on the lines of Cavour's policy in 1870, Dr. Pini resumed professional study with fresh ardour, and assisted Dr. Corradi-Pagliari and his staff in the compilation, at Milan, of the "Enciclopedia Medica Italiana." In the same city he took up the question of the treatment of rachitic children, and his energy and counsel culminated in the splendid institution erected for these little unfortunates in 1875. In 1878 he planned and organised the Royal Italian Society of Hygiene, the last meeting of which at Florence in May, 1887, was reported as a brilliant success in THE LANCET.

It was as an active promoter of cremation, however, that, in Milan particularly, Dr. Pini was most widely known. The Cremation Society founded by him in Milan in 1876 has been followed by the organisation of thirty-six others, mainly in Upper Italy, of which fourteen possess a highly efficient crematory furnace. In 1881, when a renewed attack was made on this mode of sepulture by the Florentine clergy, he delivered in the Circolo Filologico of the Tuscan capital a powerful defence of it, which will long be referred to by all who require from time to time to recapitulate the arguments for its vindication.

Dr. Pini was indefatigable in devising medical charities and putting them into working order. His Filantropia senza Sacrifici (Philanthrophy without Sacrifices) has been eminently useful in supplying relief to the deserving invalid poor, consisting as it does in an organisation for collecting all waste paper from cities and communities, storing it, and then disposing of it, the proceeds being applied to a well-constituted charity. Other associations as serviceable in their way were also set on foot by him, such as the Soccorso Fraterno (the Brotherly Aid) and the Asili Notturni (Night Asylums).

As an author on special subjects, Dr. Pini was diligent and judicious, as evidenced by his work in Schivardi's "Annuario delle Scienze Mediche," and in the "Dizionario Etimologico di Scienze Mediche e Veterinarie," which he edited in conjunction with Schivardi, Longhi, and Fivinazzi. With all this he found time to assist on many commissions (particularly on hygiene), of which the Pellagra Commission was among the most memorable; and his abilities on such occasions were so esteemed by the Government that it associated him with Bertani as representative of Italy on the Jury for Hygiene and Medicine in the Paris Exposition of 1878. For his services he was presented by the French Government with the badge of Officer of Instruction, and by that of Italy with the Cross of SS. Maurice and Lazarus. One of Dr. Pini's last works was a practical paper on bread-making, addressed to the Milanese bakers in May, 1887, showing how the nutrient elements in bread could best be conserved and utilised; and this in view of practical State measures against *pellagra*. He died at the early age of forty-one, on September 25th, at his residence in the Sifilicomio in Milan, of which he was director, regretted by all, even by the Church party who opposed him, as one whom Italy and humanity could ill spare.

JAMES THOMAS CARTER, F.R.C.S. EDIN., &c.

WE regret to record the death, at the age of thirty-seven of Mr. James Thomas Carter of Glasgow. Mr. Carter was Lecturer and Demonstrator in Anatomy in the Western School of Glasgow, having previously distinguished himself in Edinburgh as chief assistant and demonstrator in the large classes of Mr. Symington in Minto House. In Glasgow his success was rapid and great. In one year he had over a hundred students. His knowledge of anatomy was exact and wide, and he had the happy power, not given to all great anatomists, of being able to teach it. He was little known to the public, but was beginning to make a name in the medical societies of Glasgow by work of great promise. Mr. Carter's general qualities as a man and a teacher were such as to make his early death a grievous event to all concerned in medical education. He died from scorbutus and pernicious anæmia. Mr. Carter was a Lancashire man, and educated at Owens College and Edinburgh.

VITTORIO GIUDICI.

The autumnal mortality among our Italian brethren has been heavy this year, and to the three distinguished names already recorded must be added a fourth—in some respects the most distinguished of all—Vittorio Giudici, major-general on the hygienico-military staff. He succumbed on the 3rd inst. to cerebral paralysis in Rome.

Born at Nesso on May 13th, 1819, he was in the revolutionary year of 1848 enrolled as a volunteer in the Lombard contingent under the Provisional Government, and on June 5th of the same year he obtained the rank of lieutenant. In 1849 he passed as surgeon-major into the 6th Regiment of Infantry in the Sardinian army, and thereafter rose steadily through every rank of the medico-military career. It was in the campaign of 1859, when Sardinia and France took the field against Austria, that he signalised himself most conspicuously, having obtained,

Digitized by Google

after the sharp encounter at Montebello on May 29th of that year, honourable mention for valour under fire, and again, on June 24th, he received a like tribute after the fiercely contested battle between King Victor Emanuel and General von Benedek at San Martino. From Jan. 10th, 1880, he had been attached to the Commission of Military Hygiene, and from the January of 1883 he held the highest office in the department. As a deputy in the Italian Parliament he took an able and effective part in all sanitary legislation, particularly as it bore on the health and physical well-being of the soldier. He had, shortly after his election in 1859, to resign his seat, his official appointments bringing him under the law of "incompatibility," as it is called; but this was for a brief interval. As soon as he legally could, he offered himself to the constituency of Como, and continued to represent it till the day of his death.

His death is deeply deplored by his brother deputies, as well as by the whole profession throughout Italy. His funeral, on the 5th inst., was an impressive one. From his house in the Via Balbo on the Viminal it proceeded through the principal streets between that quarter and the cemetery at Campo Verano, the route being lined with troops and spectators, and the highest posts in the army, the navy, the legislature, the universities, and the professions being all represented. The Duke Torlonia placed a wreath of fresh flowers on the bier, and, at the halt in the Piazza dei Termini, the usual *oraisons funèbres* were delivered in the name of the army and of the Chamber of Deputies.

Medical News.

ROYAL UNIVERSITY OF IRELAND. — The following have passed the Second Examination in Medicine of the University:—

UPPER PASS DIVISION.—Isaac Banks, Robert Carse, Joseph Eldon, William Hartland, John Hennessy, Thomas McDermott, John McNamara, Arthur Mitchell, William O'Donnell, James Taylor, James Tracy.

PASSED.—J. Adrian, R. Barnes, Helton Bernard, F. Bradshaw, W. Bullen, James Cluff, F. Dick, C. Donovan, P. Donovan, R. Dudgeon, W. Hughes, J. Kelly, D. Leahy, J. Loftus, R. Lyons, W. McCallin, A. McComisky, J. McLeish, C. McVicker, M. Mahony, H. Morton, T. Mulholland, J. Nevin, J. Obre, J. O'Leary, A. P. O'Toole, J. Richey, A. Robb, J. Steen.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—At the recent examination for the degree of Master in Surgery the following candidate satisfied the Examiners, and was awarded First Class Honours:—

Thomas Horrocks Openshaw, M.B., B.S., F.R.C.S.

PHARMACEUTICAL SOCIETY OF IRELAND. — At the October Examinations the following obtained the licence of the Society:—

Alexander Ferguson Allan, Robert Wagner Maxwell, Samuel Robb, John Simpson Robinson, Robert Joseph Ronselle, and Edward Walker.

DR. ULLMANN, in a report he has just issued on some experiments he has conducted with a view to test the efficacy of Pasteur's inoculation method, pronounces in favour of the system as a preventive of hydrophobia.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—The inaugural meeting of the above Society will take place on Oct. 28th, when an address on Cremation will be given by Sir Spencer Wells, Bart.

FIRE AT A LUNATIC ASYLUM.—A telegram from Cleveland, Ohio, announces that a fire has occurred at the lunatic asylum at that place. Six of the inmates perished in the flames, while three others were injured.

ENTRANCE SCHOLARSHIPS.—At *St. Thomas's* Hospital Medical School, the first Entrance Scholarship in Natural Science (value 125 guineas) has been awarded to Mr. James Edward Harris, and the second (of the value of £60) to Mr. William Bamford Winston. Messrs. J. H. Fisher and B. G. Heather were specially mentioned. Eight others obtained marks qualifying for a scholarship.—At the *Charing-cross* School the entrance scholarship of £30 has been awarded to Mr. Harold Gardner, and that of £20 to Mr. Dudley C. P. Taylor.—At the *Westminster* School the Entrance Scholarship, value £80, has been awarded to Mr. Alfred Milne Gossage.

ON the 12th inst. Lord Stanley of Preston opened the new park, baths, and infirmary presented to Northwich by the late Mr. Verdin, M.P.

NAVAL MEDICAL SUPPLEMENTAL FUND. — At the quarterly meeting of the directors of this fund, held on the 11th inst., Sir W. R. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of £64 was distributed among the several applicants.

POISONING BY OYSTERS.—Several cases of poisoning by oysters are reported from Rotterdam. The first symptoms came on from sixteen to twenty hours after eating the molluscs. None of the cases have proved fatal.

NEW MEDICAL MISSIONS IN LONDON.—According to *Medical Missions at Home and Abroad*, two new medical missions have recently been opened in London, one in Canning-town under Dr. Frank Laird, the other in Brontë-place, East-street, Walworth, in connexion with the "Mildmay" workers under Dr. Henry Marston.

AT the annual meeting of the supporters of the Grimsby Hospital on the 3rd inst., it was reported that the debt on the institution amounted to nearly £1000. It was resolved that, with the consent of the donors, part of the Jubilee Endowment Fund should be used to liquidate this encumbrance.

DERBYSHIRE INFIRMARY SATURDAY FUND.—At the recent annual meeting of the committee of this fund, the balance-sheet presented by the secretary showed the total receipts for the year to have been £992, against £1026 last year, the expenses having been £66. Considering the depression in trade, the figures were regarded as satisfactory.

TEMPERANCE AND PHYSIOLOGY. — It is announced that a course of eight Friday Evening Popular Lectures will be given by Dr. W. B. Richardson, F.R.S., during the coming winter, commencing October 14th, at the Memorial Hall, Farringdon-street, E.C. The lectures will be illustrated by specially prepared diagrams shown by oxy-hydrogen lime-light apparatus.

BROCA'S STATUE.—The statue of Broca which is to be erected at Sainte Foix is to be of bronze, and not of zinc as originally proposed. The cost of this material being very high, the committee is obliged to appeal for more funds. The sculptor's charges will fortunately be saved, as the Anthropological Society, which has just erected a statue of Broca in Paris, has kindly promised the use of the mould.

BIRMINGHAM ORTHOPÆDIC HOSPITAL. — At the annual meeting of the supporters of this institution on the 7th inst., it was reported that the building required several structural alterations to render it satisfactory, and plans and estimates for these alterations have been considered by the committee. The scheme embraces new wards, operating theatre, increased sleeping accommodation for the staff, and a much-needed mortuary, the estimated cost being nearly £500. As an alternative plan, it was suggested that £2500 should be raised by debentures at 4 per cent., guaranteed on the present income, and that a new hospital should be at once built. Should this latter scheme promise to prove successful, it was decided that the committee should be recommended not to carry out the improvements mentioned.

ST. JOHN AMBULANCE ASSOCIATION.—The report of this Association just published shows that upwards of 270 administrative centres have now been formed in all parts of the world, while the detached classes are numbered by hundreds. During the past twelve months 17,718 certificates have been issued, being an increase of 5928 over any previous year, making a grand total of considerably over 110,000. Prominent features of the movement are the continued extension of classes for railway *employés* and police and county constabulary, and the increased number of ambulance and nursing "corps" formed among certificated pupils both at home and in the colonies. Detailed statements bear testimony to the good service frequently rendered by members, and reports are included showing the usefulness of the stations formed at the Colonial, Indian, and Liverpool Exhibitions, while a special letter of thanks from Sir Charles Warren records the valuable assistance rendered by the "Invalid Transport Corps" on Jubilee Day and other recent occasions.

Digitized by Google

THE Emperor William has sent a sum of 10,000 marks to be distributed among the necessitous people in the cholera stricken district of Messina.

A GIRL aged thirteen years died in the Liverpool Royal Infirmary on Wednesday from the effects of burns received on the previous evening by the upsetting of a paraffin lamp. She was terribly burnt.

FEMALE MEDICAL MISSIONARY INSTITUTION FOR AGRA Dr. Valentine, the principal of the native Medical Missionary Institute for training young men as native medical missionaries in Agra, is very anxious to see a similar institute established for female agents. The head-quarters of Lady Dufferin's National Association for supplying Female Medical Aid to the Women of India is to be at Agra, but those employed by that association will be under a solemn obligation to abstain from saying anything about Christianity to their patients, so that missionary societies will have to make their own arrangements for female medical evangelists. There is no reason, however, why these should not be trained in professional knowledge in the Government Medical School at Agra together with Lady Dufferin's native medical women.

PRESENTATION. — During the early months of the present year, an ambulance class was conducted in the spacious club room of Messrs. Frederick Braby and Co., Limited (the corrugated iron manufacturers), of Deptford, by Mr. W. Davies, surgeon, of King's-road, Peckham, the class being for the *employés* of Messrs. Braby, twenty-two of whom went up for examination and obtained certificates. On the 1st inst. the annual meeting of the library and club belonging to the firm was held, and on that occasion the members of the ambulance class presented Mr. Davies with a very handsome large writing desk, made of Italian walnut, completely bound in brass, and beautifully fitted, having on it a brass plate bearing the following inscription artistically executed: "Presented to Dr. Wm. Davies, in appreciation of his services, by the members of the St. John Ambulance class. —Messrs. Frederick Braby and Co., Limited, October 1st, 1887."

ANOTHER DEATH FROM HYDROPHOBIA AT LIVERPOOL.—An inquest was held on the 12th inst. by Mr. Brighouse, county coroner, upon the body of a boy, aged two years and seven months, residing in Bootle. On the 17th ult. the deceased was bitten near the ear by a collie dog. Carbolic acid was applied to the wound, but no doctor saw the child until five hours after, when Dr. Wills of Bootle saw and treated the case. Deceased apparently recovered, but on the 9th inst. symptoms of hydrophobia appeared. Dr. Wills was called, and found saliva running from the mouth; the temperature over 120°; and food and drink refused. Death occurred on the 11th inst. The case was seen also by Dr. Clampitt, who confirmed the diagnosis. Dr. Wills gave evidence at the inquest, and a verdict of death from hydrophobia was returned. A police inspector stated that nothing was known of the dog in question. A number of dogs found straying within the last two months have been destroyed.

THE HOSPITALS ASSOCIATION.—On the 12th inst., at the Society of Arts, Sir Andrew Clark presided over the first meeting of the session of this Association, when the subject of the provision of help for nurses was discussed in a paper by Mr. H. C. Burdett, under the head of "A National Pension Fund for Nurses and Hospital Officials." Sir Andrew Clark, in opening the proceedings, said that the Hospitals Association was founded to help in the great work of hospitals, with the desire to make, if possible, their work more economical and, at the same time, more efficient, and also to obtain the registration of nurses, who formed so important a part of hospital administration, and he insisted that this registration was necessary for the security of nurses who were of character competent and of proved loyalty to their duty. Mr. Burdett stated that during the last five years there had arisen a feeling in favour of the establishment of a fund to provide on provident principles for the relief in sickness and age of those engaged in ministering to the requirements of the sick when incapacitated from further labour in the cause of suffering humanity. There was now reason to believe that the time had arrived when the outlines of a scheme which would adequately meet the requirements of those referred to might be usefully formulated and discussed. A discussion followed, and eventually, on the motion of Lord Sandhurst, Sir Andrew Clark was requested to lay before Her Majesty the whole subject of establishing this fund.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BOWKER, EDWARD H., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Fylingdales District of the Whitby Union.

BROCKWAY, ARCHIBALD B., M.R.C.S., has been appointed Assistant Medical Officer to the South-Eastern Hospital, Metropolitan Asylums Board, New-cross.

CAMPBELL, WALTER SCOTT, M.B., C.M. Univ. Glas., has been appointed Public Vaccinator for the Crediton District of the Crediton Union, vice J. A. Edwards, resigned.

COONEY, JOHN EDWIN, L.R.C.P., D.P.H. Camb., has been appointed District Medical Officer for the Fulham Union, No. 2 District, vice T. A. Appleton, M.R.R.S., transferred to No. 1 District.

LEWIS, JOHN NICHOLLS, M.R.C.S., L.R.C.P.Lond., L.S.A., has been appointed Resident Clinical Assistant to the East London Hospital for Children and Dispensary for Women, Shadwell, E.

MILNER, E. TAYLOR, M.A., M.B.Oxon., M.R.C.S., Resident Medical Officer of the Convalescent Hospital, Cheadle, in connexion with the Manchester Infirmary, has been appointed Resident Surgical Officer to the Royal Infirmary, Manchester.

PHILPS, PHILIP, M.R.C.S., L.S.A., has been appointed Medical Officer for the Fourth District of the Faversham Union.

ROSS, JAMES, LL.D., M.D., C.M. Aber., F.R.C.P. Lond., has been appointed Joint Professor of Medicine at the Owens College, Manchester.

SEALY, FRANCIS M., M.R.C.S., L.S.A., has been appointed Medical Officer for the Sutterton District of the Boston Union.

SMYTH, ROSS V. B., M.A., M.D., B.Ch.Dub., has been appointed Medical Officer for the Third District of the Barnet Union.

THOMSON, J. A. M., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Workhouse of the Bradford (Wilts) Union.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to rename the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary £150 per annum (with an allowance of £30 per annum for cab hire), and furnished rooms, fire, lights, and attendance.

BLACKBURN AND EAST LANCASHIRE INFIRMARY.—Junior House-Surgeon. Salary to commence at £30 per annum, with board, washing, and lodging.

CARNARVONSHIRE AND ANGLESEY INFIRMARY, Bangor.—House-Surgeon. Salary £100 per annum, with board and lodging.

CUMBERLAND INFIRMARY, Carlisle.—Assistant House-Surgeon. Salary £40 per annum, with board and lodging.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Registrar and Chloroformist. Salary £30 per annum, with an additional £20 if the post is held for twelve months.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Junior Resident Medical Officer. Salary £50 per annum, with board and residence in the hospital.

HOSPITAL FOR WOMEN, Soho-square, W.—Two Clinical Assistants.

INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Senior House-Surgeon. Salary £60, rising to £70, with board and residence.—Also Junior House-Surgeon. Salary £50, rising to £60.

LINCOLN UNITED FRIENDLY SOCIETIES' DISPENSARY.—Resident Medical Officer. Salary £200 per annum, midwifery and vaccination fees, coals and gas, with house free of rates.

NORTH LONDON CONSUMPTION HOSPITAL.—Physician.

ROTHERHAM HOSPITAL.—Assistant to the House-Surgeon. Rooms, commons, and washing, in lieu of salary.

ROYAL HANTS COUNTY HOSPITAL, Winchester.—House-Surgeon. Salary £100 per annum, with board and lodging.

ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, E.C.—House-Surgeon. Salary £50, with board and residence in the hospital.

ST. MARY'S HOSPITAL, Quay-street, Manchester.—House-Surgeon and Resident Obstetric Assistant Surgeon. Salary for the first year £130, with board and residence.

TAUNTON AND SOMERSET HOSPITAL.—Honorary Surgeon.—House-Surgeon. Commencing salary £100, with board, lodging, and washing.

VESTRY OF ST. MARY, Newington.—Medical Officer of Health. Salary £300 per annum.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House-Surgeon. Board, lodging, and attendance. House-Physician. Board, lodging, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

ADAM.—On the 6th inst., at 70, Fernhead-road, W., the wife of C. Denovan Adam, L.R.C.P., M.R.C.S., of a son.

BAKER.—On the 8th inst., at Dawlish, S. Devon, the wife of A. De W. Baker, L.R.C.P.Lond., M.R.C.S., of a son.

CHAVASSE.—On the 9th inst., at Barnt-green, Worcestershire, the wife of Thomas Frederic Chavasse, M.D., of a son.

GUBBINS.—On the 7th ult., at Naini Tal, North West Provinces, India, the wife of W. L. Gubbins, Surgeon-Major, Army Medical Staff, of a son.

HARRIES.—On the 6th ult., at Suffolk-street, Pall-mall, the wife of Arthur Harries, M.D., of a son.

HARBORD.—On the 26th ult., the wife of H. Augustus Harbord, M.R.C.S.Eng., L.R.C.P., of 36, Bedford-square, W.C., of a son.

HUME.—On the 6th inst., at Sutton-place, Hackney, the wife of Walter A. Hume, M.R.C.S., L.S.A., of a son.

HUNTINGTON.—On the 6th inst., at 59, South-street, St. Andrews, the wife of W. Huntington, M.R.C.S., L.R.C.P.Lond., of a daughter.

KANE.—On the 7th inst., at Lanherne, Kingston-hill, the wife of N. Henry K. Kane, M.D., of a son.

MACKERN.—On the 7th inst., at Cambridge-street, Hyde-park, W., the wife of John Mackern, M.D., of a daughter.

REID.—On the 4th inst., at Oakley, Kirkcudbright, N.B., the wife of W. S. S. Reid, M.B., of a son.

SUTTON.—On the 8th inst., at Bagdad, the wife of Hy. Martyn Sutton, M.R.C.S., L.R.C.P., Medical Missionary, C.M.S., of a son.

WHITE.—On the 7th inst., at Harley-street, the wife of W. Hale White, M.D., of a son.

MARRIAGES.

DALZIEL—WADDELL.—On the 6th inst., at Palmerston-place Church, Edinburgh, T. Kennedy Dalziel, M.B., C.M. Ed., to Madge, third daughter of John Waddell, Esq., of Inch, and Belford-park, Edinburgh.

DANIELL—HENDERSON.—On the 6th inst., at All Saints', Wandsworth, by the Rev. William Reed, Vicar, Richard Thomas Daniell, M.B.T.C.D., F.R.C.S.I. (Exam.), to Margaret Marion, fourth daughter of the late Robert Henderson, of Leghorn and Glasgow. No cards.

HORSLEY—BRAMWELL.—On the 4th inst., at St. Margaret's, Westminster, Victor Horsley, F.R.S., to Eldred, eldest daughter of Sir Fredk. Bramwell, D.C.L., &c.

VENN—STEVENS.—On the 8th inst., at Holy Trinity Church, Tulse-hill, by the Rev. N. A. Garland, M.A., Vicar of St. Matthew's, Brixton, assisted by the Rev. W. C. Moore, M.A., Vicar of the Parish, Albert John Venn, M.D., of 27, George-street, Hanover-square, to Emma, daughter of the late William Stevens, of Springfield, Tulse-hill.

WATKINS—CHAMBERS.—On August 10th, at St. Andrew's, Summer-hill, New South Wales, by the Rev. James Clarke, Sydney C. Watkins, M.R.C.S.E., of Manly, New South Wales, to Florence Bessie, daughter of Thomas Chambers, M.D., of Sydney, formerly of Chester-square, London.

DEATHS.

MACGRATH.—On the 7th inst., at Colville-terrace, W., Wm. Michael MacGrath, M.K.Q.C.P.I., L.R.C.S.I., aged 46.

MARTIN.—On the 28th ult., at 13, South-place, Kennington-park, Hon. Brigade-Surgeon James Martin, aged 57.

ROOKE.—On the 8th inst., at Redhill, B. P. Rooke, M.D., formerly of the Medical Department, Bombay Army, aged 86.

SPOONER.—On the 10th inst., at 1, Maida Vale, London, Edward Oke Spooner, F.R.C.S., late of Blandford, Dorset, in his 80th year.

TOWNE.—On the 9th inst., at his residence, Rectory-road, Stoke Newington, Alexander Towne, jun., M.R.C.S., L.S.A., aged 47.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE DOSAGE OF COCAINE.

G. P.—It is impossible to name a dose that is safe for all individuals, since many persons are unfavourably affected by even small quantities of cocaine. As a general rule no external application weaker than 20 per cent. is satisfactory. Taken internally, cocaine may be exhibited in doses of from a quarter of a grain to a grain. For hypodermic administration a 10 per cent. solution should be employed, but not more than ten minims used. In operating for fistula, for the removal of small tumours, or for circumcision, first paint the surface with a 20 per cent. solution, then wait five minutes; after this inject hypodermically a minim or two of a 10 per cent. solution by various punctures around the seat of operation. To extract teeth under cocaine, at least a grain must be injected into the submucous tissues by three punctures opposite the root or roots of the tooth to be removed. Operate ten minutes after this. Great care is needed, as cocaine produces faintness, and in some persons a degree of collapse very alarming, and not devoid of danger. Cocaine rapidly develops fungus, which renders its solutions dangerous.

Mr. Lawson Tait (Birmingham).—We shall be glad to receive a report of the case mentioned by our correspondent.

Mr. V. B. Clarke will find a notice of the matter in our present issue.

EXAMINATIONS AT THE APOTHECARIES' HALL.

To the Editors of THE LANCET.

SIRS,—As a regular subscriber, allow me to point out through the medium of your journal the unbusiness-like way in which examinations are conducted at the Apothecaries' Hall. As I possessed the M.R.C.S. only, I entered for the Materia Medica, &c., of the Hall, in order to obtain the L.S.A. to register. Accordingly on Wednesday last I presented myself for the written papers, and some eighteen of us were then told to be present next day at 2 o'clock for Practical Chemistry, to be followed by the complete *viva voce*. This we accordingly did, and at 3 o'clock we were marched into a room where we were kept till 6 P.M., before a single examiner arrived. Imagine then in what a nervous state most of the candidates were, and little wonder if some were too muddled to answer properly. Most of us were asked which hospital we came from—a question I consider highly improper. We were then all kept till the result of the whole examination was arrived at (about 8 P.M.), and though I happened to be one of the fortunate ones, I cannot help thinking that with your powerful aid something could be done to make the Hall examinations more satisfactory.—I am, Sirs, yours truly,

Oct. 7th, 1887. M.R.C.S.

OMEIRE, AN AFRICAN MILK DRINK.

HERR MARLOTH describes in a German Pharmaceutical journal an African milk drink, called "omeire," which he saw prepared by the natives of the Herero tribe, who employ themselves almost entirely in rearing cattle, some of the chiefs possessing as many as 10,000 head. They do not, except on festival occasions, slaughter them, but live on their milk. The omeire is prepared in the following manner:—Fresh milk is poured into calabashes which have not been washed since the operations of the previous day, and which therefore contain some milk. A number of these calabashes are connected together by a network of strings, so that a man sitting on the ground can keep them all in a continual state of agitation. This goes on for from one to three hours, according to the heat of the weather, the fermentation process, of course, progressing more rapidly when it is hot. The omeire is then finished. It is a somewhat thick, half-curdled fluid, something like buttermilk, with a slightly acid and pungent, but very agreeable, taste. When kept it becomes more acid. Indeed, Herr Marloth found that when it was twenty-four hours old it set his teeth on edge. The natives, however, seem to prefer it when it is very sour. He was not able to examine omeire chemically on the spot, but brought some home with him, into which he had put salicylic acid thirty hours after it was made, in order to prevent any further alteration. This he found contained 0·007 per cent. of alcohol; but he thinks it probable that in the fresh state a larger proportion of spirit exists in the drink, which on keeping is very quickly converted into acetic acid.

X.Y.Z.—The answer to our correspondent's questions can scarcely be given by anyone but himself, so much depends on his own estimate of the value of his time. Besides there are no data on which to estimate the work of such an appointment. It would be better to defer fixing the remuneration for a time.

Dr. Pedro S. de Magalhaes (Rio de Janeiro).—We have been unable to find any further reference to this subject in the writings of helminthologists.

R. H.—Sir E. H. Sieveking's little work, "Medical Advice on Life Assurance," would no doubt answer the purpose.

Mr. R. H. Wagner.—We cannot insert any more letters at present on this subject.

"THE DUODENUM: A SYPHON TRAP."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Aug. 13th last, on page 308, Mr. Collier makes an ingenious comparison between the duodenum and a syphon trap, and tries to explain that the curve of the duodenum serves the important function of a syphon trap in the human economy, by preventing fetid intestinal gases from ascending into the stomach and escaping by the mouth. Being somewhat in arrears in my reading, I regret I did not notice the interesting article earlier. As I feel somewhat puzzled and am not satisfied with the trap theory, I would consider it a great favour if Mr. Collier or some of your numerous readers would be pleased to enlighten me on the subject. I can bring myself to imagine the curve of the duodenum acting as a syphon trap, in the erect or sitting attitude, when its curve is directed downwards, but I do not see how it can serve as such while one is lying prone, or supine, or to his left. Furthermore, disregarding the peristaltic and propulsive action of the intestines, I can also imagine that the curve is "kept constantly full of fluid" discharged from the common bile-duct so long as the trunk is erect, and the curve looking down; but I fail to understand how the fluid would keep at the curve to check the passage upwards of the gases when any other ordinary posture is assumed. In other words, a syphon trap has always its curved tube directed downwards, to retain the fluid and resist the entrance of gases. If turned sideways (i.e., if put in a horizontal plane) or with its curve directed up, the fluid would run off, and it would cease to be a trap. This, I imagine, is exactly what would happen in case of the curve of the duodenum, more or less, when one lies down on his back, or face to his side. The curve, though constant, does not adapt itself to the ordinary postural changes so as to be a good trap always; and fetid gases would certainly find plenty of opportunities to get into the stomach, and thence further on. The constant presence at the curve of secretions from the liver and pancreas, in quantity more than could be accounted for by its proximity to these, and sufficient to fill it up so as to efficiently obstruct the gases reaching the stomach, has not been demonstrated. Again, the intestinal walls are distensible, and the fluid at the curve in any quantity cannot of itself withstand the pressure of gases liberated below. No provision exists resembling a ventilating trap to meet the exigency of extraordinary gas pressure as would be met with in special conditions giving rise to intestinal obstructions. What is there to prevent fetid gases under high pressure displacing the fluid and gaining the stomach? Add to this the reversed peristaltic action present at times. This would cause the fluid at the curve to regurgitate into the stomach and upwards. It can easily be imagined how powerful inverted peristalsis is when one sees injections being occasionally vomited. When thus the fluid is carried off from the duodenal trap, what is there to oppose the gases making their way to the stomach?

I remain, Sirs, your obedient servant,

F. S. DAVAR, L.M. and S. (Bombay).
Assist. Surg. Sirsi Charitable Dispensary.

Sirsi, Bombay Presidency, Sept. 19th, 1887.

"THE RADICAL CURE OF RUPTURE."

AN American is at present making the most benevolent attempt to convince the British public that he is in possession of a radical cure for hernia, and he is circulating advertisements and a book which are meant to convince the most doubting. The book certainly does tell some wonderful stories. Amongst other feats a testimonial to this great genius, "Dr. Sherman," is produced, purporting to be from *The Lancet*, 1874. We need not say that we never published such a thing. If all the other testimonials are equally incorrect the public is to be pitied. Mr. Sherman may say it is some other journal of the same name from which he quotes. That will not avail him with honest people in this country, who, reading in a book which he puts into their hands a quotation from *The Lancet*, will certainly construe it to mean THE LANCET of England. A word to the wise is enough.

Enquirer.—Such qualifications do not justify the title mentioned. There are no legal difficulties in the sense that any legal action would be likely to follow.

Dr. Perdigao (Porto).—We cannot exchange.

"LEICESTER PROTECTED BY VACCINATION."

To the Editors of THE LANCET.

SIRS,—Your special commissioner, in his article on "Leicester and its Immunity from Small-pox," published in THE LANCET of June 5th, 1886, says:—"Tell it not in Gath—but it is even so,—Leicester owes its protection, even with all its boasted and really good sanitary arrangements, to VACCINATION! or rather, I should say, to *revaccination*. All the persons in the house of the patient are vaccinated or revaccinated." What is this statement based on? Simply on intimation of the recently appointed medical officer of health that on the twenty-fifth importation of small-pox during nine years *two* only out of nearly a dozen persons who came in contact were induced to submit to the operation. Even the nurse attending the case was not revaccinated. After a careful search through the medical reports during nine or ten years I cannot find a word about the vaccination or revaccination of a single individual during twenty-four importations of small-pox. The only reference is that in the report of 1886 on the twenty-fifth importation. The only measures recorded are prompt isolation, quarantine, disinfection, and sanitation. Quarantine is optional, and instances of refusal have been known; but usually the people cheerfully agree to it, and they doubtless would elsewhere quite as readily as they submit to vaccination.

The following extracts from health reports confirm what I have said. In 1883, after recording seventeen importations of small-pox, Dr. Johnston says: "Notwithstanding this large number of importations the disease has always been stamped out. ..... The continued exemption from small-pox experienced in Leicester under so many instances of its importation is highly satisfactory, and is *altogether due* to the success which has hitherto attended the efforts of the health committee in securing not only the immediate reporting, but also the prompt removal to hospital, of all the cases as they come under notice." In 1884 three outbreaks are recorded. Dr. Johnston says: "Owing to the immediate removal of all the inmates of each house where the disease appeared to the fever hospital, together with the thorough disinfection and lime-washing of the infected houses, the further spread of the disease was arrested." The further part of the report practically repeats the above. In 1885 the report was written by Dr. Tomkins. He says: "During the year small-pox has made its appearance at four points in the town, &c. ..... By the prompt and vigilant action of Inspectors Braley and Buxton all these cases were at once removed to hospital, and those persons who were known to have been possibly infected by them were removed to the quarantine wards." In another part of the same report the Doctor says: "In the case of small-pox and scarlet fever every effort is used to induce the patient or patient's friends to avail themselves of the hospital." The 1886 report, which has given rise to all the misrepresentation, has been quoted so often that I will only give a few words: "The usual prompt measures were adopted. The patient was removed to the small-pox wards, and two other persons who had been in contact with him were subjected to fourteen days' quarantine, and were revaccinated."

In the above quotations I have given all that is said about vaccination or revaccination in the reports so far as they relate to the actual treatment of small-pox cases during twenty-five importations in Leicester for nine or ten years. I maintain that they totally refute the statement of your Special Commissioner.

Now, as to the second part of his assertion. He says: "Every person brought into contact officially with the case of small-pox—the medical officer of health, the inspectors, the nurse and matron of the infectious hospital—are all vaccinated and revaccinated." The following facts I have personally ascertained, and they may be verified if necessary. The present sanitary staff comprises the medical officer, one chief inspector, three sub-inspectors, and one office clerk, all of whom were in office at the time of your inspector's visit. Of this number the chief inspector, one sub-inspector, and the clerk have never been vaccinated since infancy, and the protection must have ceased long ago. Of the other sub-inspectors, five years in one case and two years in the other have elapsed since the operation was performed. The nursing staff consists of the matron and two nurses, who were in office at the time of your Special Commissioner's visit. Of these the matron has not been vaccinated since childhood, and nineteen years have elapsed since one of the nurses was revaccinated; the protection has therefore ceased. The other nurse was vaccinated at West Hulme Hospital on the receipt of a small-pox patient, but proved insusceptible. She states that about three weeks after proving insusceptible to vaccine she fell of variola, and had small-pox—an experience unique and interesting to the medical world. Of four nurses since appointed, two only have been revaccinated since childhood. The other person concerned is the porter at the hospital, who was revaccinated about five years since. At the last admission of a small-pox case the nurse attending was not revaccinated, although an assistant was operated upon. We have therefore in all ten persons who were in office at the time the special report was made, four of whom have never been vaccinated, and one in whom the protection has vanished many years ago. Of the remaining five, the most recent revaccination was performed two years ago, unless Dr. Tomkins has himself been revaccinated within that period. Not one of the nursing staff has been vaccinated since appointment, excepting the assistant nurse named above.

In the presence of this overwhelming refutation the question arises, Who could have given the information which led the Commissioner astray? I lay no blame upon him, excepting this—he should have exercised more care. The whole matter calls loudly for a searching investigation in the interest of all concerned.

After this I hope nothing further will be heard of unfairness or omission; and the *amende honorable* is due from any who have thought proper to insinuate a charge of *suppressio veri* against

Yours truly,
J. T. BIGGS,
Leicester, Oct. 5th, 1887. Member of the Board of Guardians.

*** We have, from an excessive disposition to give fair-play in this life and death controversy, given Mr. Biggs space which we could very ill spare for his long letter. He spoke in his letter to *The Times* of one member of the sanitary staff who had not been revaccinated. He now thinks he has discovered that four have not been revaccinated, and, with that fine confidence so lacking in experts, he puts in a fifth, "in whom the protection has vanished many years ago." He asks us to take these facts on his personal authority. He will forgive us for saying that we do not consider him a good authority on such questions. We should entirely approve of inquiry by competent and unprejudiced persons. Mr. Biggs is easily satisfied of any point on which he desires to be satisfied. For example, it was part of our Commissioner's information that all persons in Leicester in the houses in which small-pox cases occurred were promptly revaccinated. Mr. Biggs looks through the reports, and seeing little allusion to such operations in them concludes that they did not take place. Our Commissioner did not say they were reported, but that this was the practice of the medical officers of health—a statement not denied by the gentlemen affected. Mr. Biggs' letter contains important evidence of our proposition that persons not revaccinated are very liable to take small-pox when exposed to it. One of the nurses at the Leicester Small-pox Hospital had been vaccinated (revaccinated?) at West Hulme Hospital on the receipt of a small-pox case, but "proved insusceptible." In about three weeks "after proving insusceptible" "she fell [ill] of variola and had small-pox." Mr. Biggs and his school think this nurse's case a "unique" one for the study of the "medical world"; instead of which we are constantly telling him it is the common case. A person is revaccinated and does not take, and votes herself, or is voted, "insusceptible." On being exposed to small-pox she falls a prompt victim to it, clearly showing that she was susceptible, and that the vaccination was simply not effective. A man like Mr. Marson vaccinating with arm-to-arm lymph was so unerring in his skill that the nurse might go, and for fifty years did go, straight into the small-pox hospital unscathed. But most vaccinators had better see their revaccinations "take" before sending their nurses to such a fiery test. Mr. Biggs' refutation leaves a staff of officials, every one of whom he admits to be vaccinated—and many of whom he allows to have been revaccinated. It suits his convenience to say several times dogmatically of those of the staff who have not been vaccinated for years that "the protection must have ceased." Where did Mr. Biggs get his precise knowledge of the exact time at which the virtue even of a first vaccination ceases? The evidence is that at all ages it has much virtue in modifying the severity and fatality of the horrible disease. If Mr. Biggs again writes on the protection of Leicester, let him be careful to say that all persons in immediate attendance on the patients are vaccinated or revaccinated, and that Leicester herself is not yet so enlightened, or so hardy in her belief in mere sanitation, as to receive small-pox by any but vaccinated persons. We are glad to agree up to a certain point with Mr. Biggs. Good police arrangements for small-pox patients are useful. Small-pox obliterates all questions of personal liberty in the person affected, and even such a Radical community as Leicester finds ways of shutting them up. But what about the protection of the people of Leicester who go to Sheffield and the other benighted parts of the United Kingdom? Leicester people cannot be all shut up in Leicester? When the deadly disease and they, together, are abroad, what about their protection?—ED. L.

"NEW METHOD OF VENTILATION."

In reply to a correspondent of last week, we are enabled to state that the addresses of Messrs. Young and Mors are as under:—10, Cathedral-close, Lincoln, and 30, Queen-square, London, W.C.

Bones.—The placard in question is not to be commended. A true hospital should not be situated in private premises, and any advertisement of it should apply rather to the committee which guarantees it than to individual surgeons.

Cyclops.—The terms mentioned are the ordinary conditions of membership in provident dispensaries. The remuneration of medical men is not sufficient.

Mr. W. Rae.—Our correspondent should apply to any of the principal London instrument makers.

Mr. J. R. Nott.—Our arrangements will not permit us to entertain the proposal.

THE NAVAL MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—I am glad to see "Surgeon R.N." airing the subject of occasional general hospital practice as being desirable for naval surgeons after long sea service, as, though they may have many opportunities of studying subjects not met with by the ordinary general practitioner, they are likely to get wofully rusty in some of the commoner branches of the profession. Such a short course as he mentions would be an immense boon to any man who had not lost all interest in his profession. Modifications of his view of the case I fancy would be necessary, especially as regards the examination. I think that a certificate of having attended ward practice and operations given by the dean or visiting surgeons would be sufficient, as it is difficult to conceive any examination which would show the extent to which a surgeon had improved himself during the course of study; the book work, which presumably he has kept up, should have been sufficient to enable him to pass any ordinary examination in writing. Even the opportunity of a course of study in a general hospital might be dispensed with were every surgeon on return from long foreign service to be appointed for a few months, either as a supernumerary or otherwise, to one of the naval hospitals. As it stands at present, few surgeons have this opportunity, as those who have once served at a hospital are the most likely to be appointed to another, as in several cases in my mind's eye at the present moment; whilst the surgeon from the gunboat on the West Coast goes to a harbour ship, whence all important cases are immediately sent to hospital, his experience having thus a downward tendency. Haslar, Plymouth, and Chatham, to which I may add Malta, Hong Kong, &c., would give ample scope for the rusty surgeon to recruit his knowledge, especially just before his examination for staff surgeon. The cases not met with in these establishments are the diseases of women and children, subjects of but little importance in the naval service; whilst the loss of this branch is more than counterbalanced by the great number of the commoner diseases met with in the navy. Let all surgeons have an equal chance of naval hospital practice, with lectures at the naval hospitals by competent seniors, and the inexperienced naval surgeon would soon become a thing of the past.—Yours truly,

Oct. 10th, 1887. ANOTHER NAVAL SURGEON.

"THE WASTE OF LIFE BY PREVENTABLE DISEASE."

To the Editors of THE LANCET.

SIRS,—At the present time, when we are again visited by scarlet fever in an epidemic form, it may be considered desirable after perusal of the very interesting paper read before the Sanitary Institute of Great Britain by Mr. J. S. Haldane at Bolton, to make some change in the nature of the internal surface of houses. The contamination of the surface by dust was found to have an effect on the number of micro-organisms present in the rooms, a progressive contamination of the floors being the producing agent. The important deduction to be drawn from these researches appears to me to be that the surface should be of a non-porous character, rendering the absorption of noxious matter out of the question. I am, Sirs, yours obediently,

SAMUEL LEE,

Barking, Sept. 29th, 1887. Medical Officer of Health.

CATARACT OPERATIONS.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly give me the usual percentage of success in cataract operation with Graefe's modified operation or the operation most approved of at present? If the percentage of success from the hands of all operators in the Moorfields Eye Hospital for the last five years be given, this will suit my purpose. May I ask if a surgeon who gets a percentage of only seventy-four successful cases is justified in continuing to operate for cataract?—I am, Sirs, yours faithfully,

Sept. 20th, 1887. SAPO MOLLIS.

SWALLOWING A COIN.

To the Editors of THE LANCET.

SIRS,—The following case may be deemed sufficiently interesting to be placed before the readers of THE LANCET.

A child aged six swallowed a bronze halfpenny on Sept. 26th last, and passed it in stool on Oct. 3rd. The coin thus took nearly eight days to pass. No inconvenience was perceived. No treatment except as thick food as a child of that age could take was used. The coin was blackened on the surface. I am, Sirs, yours faithfully,

Oct. 10th, 1887. H. F. S.

THE VALUE OF SHORTHAND TO THE STUDENT AND PRACTITIONER OF MEDICINE.

To the Editors of THE LANCET.

SIRS,—That the employment of shorthand is of paramount moment to students—more especially those of medicine—cannot be gainsaid. I do not think it is in use much by London students, at any rate, at the cliniques (so far as I have been able to observe), while at Edinburgh I have been surprised at the diligence with which *verbatim* reports are taken of systematic lectures and cliniques, and the students do not appear to lose touch of the gist of the professor's teaching. And not only are *verbatim* notes taken at the University classes there, but diagrams made by the professors are rapidly copied beautifully. The diagrams are made on the board by different coloured chalks, and these are copied by the same coloured pencils. These notes are afterwards rendered into longhand, the drawings reproduced, and the mere rendering and reproduction suffice in a great measure, as I learnt, to impress and digest each individual lecture. A great many of these students had, as I learnt, previously employed shorthand in the University classes for Arts and Science degrees, as a great number of these are graduates in Arts and Sciences (Masters of Arts and Bachelors of Science), so that it comes like A B C to them to take down every word as uttered by the professor, notwithstanding the rowdyism of those who occupy the higher and more distant benches in the lecture theatres. It is of greater importance there, more particularly in certain subjects, to master the professors' lectures rather than read standard works. The diligent and able student not infrequently makes a double use of the shorthand system by reproducing neatly, or getting them copied at some of the University booksellers', and selling the lectures, word for word almost, and fully illustrated, for instance, the botany, natural history, pathology, and other lectures from large plates hung up or drawings made previously to the lecture by the professor or his class assistant. The best students go to the lecture room a long time beforehand to copy the diagrams, synopsis of the lecture, &c. Many of the students, however, who do not know shorthand still take almost *verbatim* notes by longhand. There is no doubt that shorthand is of great service in practice, more especially in the consulting room, where the physician can take notes fully as he is questioning and examining, and will be of great avail if the same patient consults the physician after a distant period again; and also for the employment of these notes afterwards for clinical study.

Dr. Gowers' paper, published in THE LANCET of Oct. 8th, is well worthy of the close attention of students, who should certainly strive to master Pitman's shorthand system, which is the one, I believe, mostly adopted by reporters on the newspaper press, who can write at the rate of from 200 to 250 words a minute easily. The correction, revision, and rendering into longhand and preparation for the press do not take much time. Many of the gentlemen of the newspaper press who are rapid *verbatim* reporters are excellent descriptive writers, and can summarise or rapidly write leaders from their own shorthand. This being so, the medical student can afterwards summarise the lecture and thus omit repetitions. Two students, who are friends, can both take shorthand notes, and afterwards compare and supplement deficiencies. I am, Sirs, yours truly,

South Kensington, Oct. 7th. JOHN LUCAS, M.D.

ANTIPYRIN IN MIGRAINE.

To the Editors of THE LANCET.

SIRS,—I was recently called to Mrs. F——, fifty-one years of age, who was suffering severely from migraine, to which she had been a martyr for several years, never having passed a single day without an attack of greater or lesser intensity. I immediately prescribed antipyrin, giving it in doses of fifteen grains three times daily. I saw her again to-day, and learned that the first dose gave marked relief, and that from the second day of the treatment up to the present time she had been entirely free from pain. Comment seems unnecessary.

I am, Sirs, respectfully yours,

Paris, Oct. 6th, 1887. EDWARD WARREN-BEY, M.D., C.M., LL.D.

NOISES IN THE EARS.

To the Editors of THE LANCET.

SIRS,—Kindly allow me to ask through your valuable journal for any hints as to treatment in a case of exaggerated noises in the ears as a sequel of severe typhoid. The fever ended early last April, but the sounds seem to have been ever present to my patient, who is a married man and a builder's clerk, aged thirty-six years. In other respects he is well, and no organic change can be detected in the ears. No treatment so far seems to touch the case. He says the noises almost drive him mad.

I am, Sirs, faithfully yours,

Oct. 8th, 1887. A SUBSCRIBER OF TWENTY YEARS' STANDING.

INSTITUTIONS FOR THE DEAF AND DUMB.

To the Editors of THE LANCET.

SIRS,—In your issue of the 8th instant, a correspondent, "B.," wishes to know of any institution where a boy who is deaf and blind may be educated. I shall be glad, if he puts himself in communication with me, to give him full information. We have had one or two similar cases, and very successfully overcame the great difficulties.

I am, Sirs, yours truly,

WM. MARTIN, Manager.

Royal Blind Asylum and School, 53, Nicolson-street, Edinburgh, Oct. 10th, 1887.

Medical Diary for the ensuing Week.

Monday, October 17.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Opening Address by the President (Dr. J. Hughlings Jackson).—Dr. Clifford Allbutt (of Leeds) will read a paper on Simple Dilatation of the Stomach.

Tuesday, October 18.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.
THE PARKES MUSEUM OF HYGIENE.—8 P.M. Mr. C. H. Cassal: Food, (including milk), Sale of Food and Drugs Act.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Hadden: Lymphadenoma.—Mr. D'Arcy Power: Congenital Umbilical Hernia.—Dr. Hale White: Carcinoma of Pancreas, and Semilunar Ganglia.—Mr. Bland Sutton: The Guttural Pouches of Horses.—Dr. Handford: Dilatation of Œsophagus.—Dr. A. H. Robinson; Aneurysmal Varix in a Stump.—Mr. A. M. Sheild: Rectal Polypus.

Wednesday, October 19.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

Thursday, October 20.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. J. Bland Sutton: Hypertrophy and its Counterfeits.
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Living and Card Specimens at 8 P.M. Mr. Nettleship: Case of Persistent Hyaloid Artery.—Mr. Gunn: Chronic Abscess of the Cornea.—Mr. Hartridge: An Unusual Appearance of the Optic Disc.—Mr. Keall (Bristol): Congenital Small Lens in one Eye.—Dr. S. Herbert Habershon: On Hereditary Optic Atrophy.

Friday, October 21.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
THE PARKES MUSEUM OF HYGIENE.—8 P.M. Infectious Diseases and Methods of Disinfection.

Saturday, October 22.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months..... £0 16 3

The Harveian Oration

DELIVERED AT THE

ROYAL COLLEGE OF PHYSICIANS

On Tuesday, Oct. 18th, 1887,

BY W. H. STONE, M.A., M.B. OXON.,

PHYSICIAN AND LECTURER ON NATURAL PHILOSOPHY AND MATERIA MEDICA, ST. THOMAS'S HOSPITAL.

NOTHING would have better pleased me, Mr. President and brother Fellows, than to have revived the ancient and time-honoured custom of a Latin Oration, such as these walls have so often echoed to; and this the more gladly from my belief that the practice tended to maintain the dignity of our College and its reputation for learning. But there is a tide in popular opinion which seems just now to be setting somewhat strongly in a direction opposite to the older and traditional cultivation, and a prepossession abroad that a knowledge of the ancient tongues on which our English language is founded is incompatible with ability to search out the secrets of nature by way of experiment. A striking refutation of the fallacy exists in the very man whom and whose labours we are met here to-day to commemorate, and whose honoured name as written in Latin by his own hand should stand in the forefront of my discourse as it does on the title-page of the manuscript: GULIELMUS HARVEIUS. I say in his own hand for, thanks mainly to the energy and labours of Sir E. Sieveking, we have now before us a noble production of his manuscript lectures delivered in 1616; not merely the *auros ekeir*, but the *autos egrapse*, the very autograph sign manual of a great mind, wherein we can read not only his verbal utterances, but can, with a little care at the same time, trace character, education, and temperament. It is just ten years since the gentleman named above announced to the College the rediscovery of the first Harveian lectures, and now the autotype copy with its transcript is fully before us. My object therefore on the present occasion will be to endeavour briefly to comment on this most interesting and unique work, and to sketch the lineaments of Harvey, self-revealed, as a scholar, a lecturer, a physicist, and as a man of genius, not to say humorous, disposition. In so doing we may gather from the *ipsissima verba* of one who "being dead yet speaketh" two lessons which, I believe, have not occupied the attention of my many far abler predecessors in this chair. First, an instruction in the art and method of lecturing, and wherein in this age of printed books it may still be of service. Secondly, what a large field of discovery and research still lies open to us, as it did to Harvey, on the borderground between physics and physiological medicine. For this reason I have ventured to give my oration the title of *Iatrophysica*, just such a word as he would, I fancy, have delighted to jot down, possibly in red ink, with his cypher appended, in some corner of his manuscript notes. For the discovery which has rendered Harvey's name famous was strictly physical, I may even say mechanical. It had, moreover, the one great element of accuracy in applied mechanics: it was computational and quantitative.

There can be little doubt that general ideas were abroad on the subject of the circulation, and that similar views, not indeed incorrect, but loose and inaccurate, had been entertained by others. Even Cesalpinus, *pace* Dr. George Johnson, undeniably had glimpses of the truth. It was, however, Harvey who first saw and proved that the problem was one of hydrostatics, and that it must be solved, and could be solved, by mechanics, and proved by numerical relations. There is a remarkable page in the Lectures, one of the best written and most legible in the book, in which this is stated with absolute clearness, and which at once disposes of any claims advanced in other quarters. It runs as follows: "Constat per fabricam cordis sanguinem per pulmones in Aortam perpetuo transferri, ita by two clacks of a water bellows to rayse water. Constat per ligaturam transitum sanguinis ab arterijs ad venas, unde A perpetuum sanguinis motum in circulo fieri pulsu cordis." The two hydrostatic conditions of the circulation are herein defined with geometrical accuracy, and read like the enunciation of a theorem in Euclid. Indeed, it is remarkable what a strong mathematical element runs through the argument of both his great treatise and of the lectures; not of course mathematics as we now understand them, for at the date of Harvey's death Newton was a boy of fifteen, but those of Euclid and of Archimedes. In the second page of the MS. work he speaks of form "ut trigonis in tetragonum," of proportion "ut diapente in diapason," the relation of the triangle to the square, of the fifth in music to the octave. An even more remarkable reference to musical ratios occurs a few lines later, "ut semiditonos diapase," like a semitone to an octave. Again in the ninth page we find "Proportio pectoris ad ventrem diapason ut 3·4 sesquitertia; pectoris ad caput 1 diapente, pectoris ad alvum 1 diapason;" both these last two ratios being expressed as fractions. We have, moreover, direct personal evidence to his studies in this direction; for Aubrey found him reading Oughtred's "Clavis Mathematica," and working the problems when he was no longer a young man. Now his strongest and most irrefragable argument for the new view of the circulation is distinctly numerical. "Supponamus," he says, "quantum sanguinis sinister ventriculus in dilatatione quum repletus sit contineat, sive ℥ij; sive ℥jss; ego in mortuo reperi ultra ℥ij." And further on the problem thus concisely proposed is continued: "Ita in homine protrudi singulis cordis pulsibus, supponamus unciam semis, vel drachmas iij, vel drachmam unam sanguinis, qui propter impedimentum valvularum in cor remeare non potest. Cor unâ semihorâ plus quam mille pulsus facit. Jam multiplicatis drachmis videbis unâ semihorâ, aut millies drachmas tres, vel drachmas duas aut uncias quinquies centum, per cor in arterias transfusam, quæ major est copia quam in universo corpore contingat reperiri. Quare concludendum si unciam transmissam contingere, libras 83 et ℥iv in unâ semihorâ transfusas esse de venis in arterias." He saw distinctly that the heart was simply a double force-pump, propelling an incompressible fluid into an equally double system of tubes; that it was the sole efficient cause of the motion thus engendered (indeed he uses the phrase "solum a corde"); that the lungs, although an air-pump of no inconsiderable power, both for compression and rarefaction, had nothing whatever to do with this; that the valves of the heart acted equally as machines to make good the dynamical advantage thus obtained, and that the quantity of fluid thus raised was incomparably greater than had been before supposed. The conception is as distinctly mechanical as that of the steam engine, or of the mechanical equivalent of heat which were to arise in later centuries. Even of this last great generalisation in mechanics he had no indistinct glimpse; for in the thirteenth page of the MS. he compares heat to a hammer. "Calor ut malleus instrumentum instrumentorum." With the working out of this complex but perfectly precise problem in hydrodynamics, came accuracy and certainty in place of theory and conjecture. "Flux and reflux" had had their day, and no more need be said of that unlucky Euripus which is fabled to have driven a great natural philosopher, Aristotle, to suicide, and which had been an incubus on science ever since.

Only twenty-six short years after the first Harveian lectures were committed to paper, and fourteen after the treatise "De Motu Sanguinis" appeared, the wondrous boy was born who was destined in like manner to penetrate another of nature's mechanical mysteries—the problem of universal gravitation. Newton was fifteen years old when Harvey died, and already studying Oughtred's "Clavis Mathematica," the very work which Aubrey found Harvey engaged upon, as above stated. As regards Harvey's classical scholarship, little needs to be added to what has already been well said. The scholar of Canterbury Grammar School and the pensioner of Caius College, Cambridge, was clearly well trained in classics, dialectics, and physics. He evidently knew Aristotle thoroughly, and often quotes him, especially the grand treatise on "Metaphysics," and the excellent book on the "Generation of Animals," a quotation from which stands on the title sheet of the Lectures. For it must be remembered, in these days of detraction, that Aristotle was no mean naturalist, and even comparative anatomist; many of his shrewd observations in this direction being sound even to the present time. "Naturæ diligentissimus investigator" are the words. Harvey also quotes the "Gorgias" of Plato, and there is a passage in the preface to his treatise "De Generatione," which so com-

Digitized by Google

pletely recalls the myth of the cave in Plato's "Republic" that it cannot be an accidental coincidence. "Hi," says he, "non veras ideas, sed falsa idola et phantasmata inanis mente concipiunt; unde umbras quasdem et chimæras sibifingunt." It is difficult also to believe that this metaphor had not been recalled to Harvey's memory by the use of it under the name of Eidola Specus, in a great work then recently produced, which overtly in its very title professed to be an extension of Aristotle's grand work on formal logic—namely, the "Novum Organon" of Bacon.

Aubrey says, in his "Lives of Eminent Persons," that Harvey understood Greek and Latin pretty well, but was no critic, and wrote very bad Latin. We are, however, now in a position to judge of this for ourselves from the real autograph. The Greek words scattered freely through the lectures are well written and spelt, though in one or more instances the first part of a word begins in Greek and finishes in English characters. But this is only on a par with the whole work, which is a canto of Greek, Latin, and English, never intended to be seen by any eye besides that of the writer himself. Yet even thus in passages they rise almost to eloquence, as in p. 47, where, speaking of the maintenance of human species by generation, in spite of the death of the individual, he says: "By the string tyed to eternity. Unde cum naturâ non potuit Individualem æternitatem, id quod potuit harum partium facultate speciem æternitatis generando sibi similem in secula. Unde sacris literis greatest blessing Issue, that thy seed shall remayne for ever." And further on: "Apparet item maribus et fœminis qui moderate utuntur never more brave, sprightly, blith, valiant, pleasant, or bewtifull," which cannot fail to remind us of the passage in the fourth Georgic of his favourite author Virgil:

> "Ergo ipsas quamvis angusti terminus ævi
> Excipiat (neque enim plus septima ducitur æstas)
> At genus immortale manet, multosque per annos
> Stat fortuna domûs, et avi numerantur avorum."

But before leaving the loving commemoration of our great benefactor, I wish to point out some evidences of his genial and even humorous temper, which must have made the lectures pleasant to listen to. At page 16, speaking of the position of the abdominal organs, he says: "Situs omnium partium certus partim incertus." Then, breaking into familiar English, he notes: "Natura Romidges (*sic*) as she can best stow, as in ships." While still on the same topic, he points out that malposition of organs occurs in "yeoung (*sic*) girls by lacing; unde cutt there laces." In another place (page 53), in describing an irreducible hernia, he says it may be filled "cum maximâ quantitate aquæ et flatus." "The man behind Covent Garden bil." At page 35 the spleen is described in man "as washous to the kitchin," and its absence in lower organisms, "Inferior kitchins need noe washhous." Lastly, "in quibus vitiatum temperamentum, Lien Major the washhous exceed ye kitchin." It is difficult to believe that the passage which follows (page 54), "Mas a vigore spiritus higher sett, unde Bastards brave men, quia magno fervore geniti vetito concubitu" is not a reflection of Shakspeare's bastard, Faulconbridge, a character which Harvey may have seen represented, even by its creator himself, at any time in the eighteen previous years. But perhaps the quaintest entry is one speaking of some rather controvertible anatomical assertions which he thus records (page 50): "W. H., a little staggerum in these." He describes the thymus gland as follows: "Thimus, sweete bread, nutt of veale, corpus glandosum molle, heare they sticke the piggg." And a little further on, speaking of some idle controversy of previous writers, he describes it "est de lanâ caprinâ," which is obviously a note jotted down from the Horatian line, "Alter rixatur de lanâ sæpe caprinâ." In an excellent account of the signs of asphyxia, he says: "Soe curst children by eager crying grow black and suffocated, non deficiente animali facultate," which again recalls to our memory Kate the Carst in the "Taming of the Shrew."

There is, however, one page of this remarkable volume which requires more than cursory notice, as beyond illustrating the character of our distinguished benefactor, which I am specially directed to do, it affords us from his example a valuable lesson for our own instruction. These are the *canones anatomiæ generalis*, rules which he evidently laid down to himself, and in which he has left us a precious legacy of advice. They are twelve in number, hastily, but evidently after mature thought, jotted down in the strange mixture of Latin and English which is throughout the book adopted. They occur at page 4:—

"Canones Anatomiæ generalis

1 shew as much vno intultu as can be
vt de toto ventre: vel toto aliquo quæ accidunt
deinde dividere (propter situs et conexiones
2 demonstrare propria filius Cadaveris
Nova vel Noviter Inventa
3 to supplye only by speech what cannot be shewn
on your own credit and by authority
4 cutt vp as much as may be in presentia ut cum
Historia peritia innotescat
5 observationes proprias et alienas recensere
ad confirmandam propriam opinionem vel obsignatis
tabulis in alijs Animalibus agere
secundum Socratis regulam: where it is farer written
vnde observationes exoticas
1 ob causas Morborum: Medicis præcipue vtilissimas
2 ob varietatem Naturæ philosophicæ
3 ad refutandos errores et proinde solvendos
4 ob vsus et actiones Invenlendas dignitates
et propter inde Colectanea
Anatomiæ enim finis partis Cognitio propter quid
Necessitas et vsus
philosophis præcipua qui inde sciunt
ad vnamquamque actiones quæ requiruntur quod præstat
Medicis item qui inde constitutionem naturalem

12 to serve in their iij courses according to the glass
1° ventris inferni nasty yett recompensed by 'admiry'
admirable variety
2° the parlor 3° divine Banquet of the brayne."

It is singular how much of this is still valuable, though written at a time when printed books were scarce, oral lectures the chief mode of teaching, and primers, text-books, compendia, with all the artillery of cram, unknown. Indeed, a direct answer is given to the paradox, which has of late obtained some vogue, and which has been fostered by examining machines miscalled universities, that lectures are useless, and that it is only necessary to ascertain that a student knows certain prescribed facts without asking how and where he learned them. Those of us who are teachers and examiners—and I am aware I am speaking before the most learned body of teachers and examiners in this kingdom—know the fallacy; it is a fallacy, moreover, chiefly in the higher branches of thought, where absolute certainty is unobtainable, and where tact, experience, and the exercise of a judicial function of the mind are necessary. It is a fallacy still more where acutely cultivated sense—the memory of the eye, of the ear, and of the touch—have to be added to these characters. As an examiner myself to this College of over seven years' standing, I feel I can often detect book knowledge and parrot-like iteration of catch-words learned by rote, but not thought out, in some voluble but superficial candidate. Indeed, Charles Dickens and Albert Smith (the latter a medical student himself, both acute observers of human nature) have each pilloried flagrant offenders in this direction with the severity and incisiveness of real humour. To these book-read anatomists and school-board paradoxists an admirable answer is given in the words, "Cutt up as much as may be in presentiâ, ut cum Historiâ peritia innotescat," that, with the description, practical experience should arise.

But it is not only the superficial and sciolistic learner who may gather lessons from this remarkable page; there is much that we as lecturers and teachers may take to heart with advantage. "To supplye only by speech what cannot be shewn on your own credit and by authority"; also, "observationes proprias et alienas recensere, ad confirmandam propriam opinionem." There is often, even at the present day, much difficulty in the full performance of the duty here so lucidly and tersely set forth—that, namely, of comparing our own with others' observations. It occurs to a great extent in the department to which the present speaker's chief attention has been devoted—that, namely, of physics. Much valuable work and information is stored away in papers read before learned societies, in small detached pamphlets, in foreign and scientific periodicals, and similar places very hard to reach for purposes of consultation. Hence follows no little repetition of labour in rediscovery,

Digitized by Google

and the consequent disappointment of perfectly conscientious observers who have unwittingly gone over the same ground as their forerunners in science. It is, moreover, from comparison of one's own views with those of previous labourers, if it be performed in a conscientious and thorough manner, that new views and ideas often arise.

It is not, however, so much in the seeking out of new facts in nature that these *canones* help us, as in the suggestions for the communication of knowledge, a function especially important in the art of medicine, because at the end of our educational chain there hangs suspended a human life. There can be no hesitation in calling this pregnant collection of maxims a treatise on the art of imparting knowledge, an art too much neglected even in the present age. For, sooth to say, Englishmen fall, I fear, somewhat behind their French and German rivals in the practice of this important function. Even their speech and articulation are often inferior, as anyone who has listened to Trousseau, Claude Bernard, or Virchow must be well aware. "Brefly and playnly, yett not letting pas any one thing unspoken of which is subject to the vew," says our thoughtful monitor. Then again, "Not to dispute confute alias quam argumentis," a quiet sarcasm on obtrusive controversialism which may go home to many a pulpit beyond this from which I have the honour to address you.

We are now in a position to gather in the fruit of our author's teaching; and first as to the utility of lecturing. We have it in his quaint language that it is justly a combination of what a book can give—namely, knowledge; with what it cannot—namely, *intuitus* or demonstration. In many subjects, in none certainly more than general anatomy, this is a point of no mean importance. The eye can assist the ear; two inlets are afforded at once to the sentient brain instead of one, and two forms of memory can be called forth. For it is a fact, though one seldom insisted on, that memory has at least as many forms as there are senses. The memory of the ear is perhaps the commonest but also the least intellectual, unless applied to harmonious sounds and melodies. Unfortunately, the mere reproduction of the dry husks of thought termed words is too much cultivated in these days of overpressure, and too little care is taken to secure the essential nucleus of the grain of thought. To the anatomist, the surgeon, and the man of science generally, the memory of the eye transcends the former. A geometrical memory, which can reproduce forms healthy or diseased, is an acquirement especially to be cultivated by the student of medicine and pathology. This is far better done in lectures than by books.

Secondly, the lecturer can keep himself abreast of all things *nova vel noviter inventa*, whereas the book, even if at first up to date, as it seldom is, soon falls back in the race and becomes ancient. There are, indeed, books, like the "Metaphysics" of Aristotle, the "Republic" of Plato, and the "Aphorisms" of Hippocrates, and more lately the "Principia" of Newton, the "Religio Medici" of Sir Thomas Browne, and the work "De Sedibus et Causis Morborum" by Morgagni, which will never grow old; but when we come to the new philosophy, and wrest daily fresh secrets from nature, the case is different. Here also the lecture far transcends the book; especially if the lecturer, standing on the brink of the precipice which separates the known from the unknown, can detail facts or deductions which he can vouch for and prove "on his own credit and authority," as saith our teacher. It is a severe labour, indeed, but a labour of love in these days of scientific progress, to keep oneself informed of all fresh truths as they arise, so as to impart them "brefly and playnly" to younger and still thirsty minds. If to these he can add *observationes propriæ*, original facts and investigations, the lecture reaches a pitch of individual interest which none but the greatest books, certainly no handbooks or manuals, can ever attain.

Lastly, the lecture, well delivered, has a greater point and flexibility than the written volume. The lecturer, like the actor, can study his audience, and wake their attention by a judicious or even humorous allusion. The manuscript before us teems with these; indeed, several have been already cited; perhaps, however, the quaintest of all occurs in the description of the diaphragm. After giving its function as a septum or partition, he mentions the old English name *midryf*, and this he compares to the *shere* or *shire reva* or *reeve*, a well-known county officer at the time, and says, "his office serving to both belly and lungs he is stickler between them." There can be but little doubt that a smile passed over the grave countenances of the assembled physicians at this homely allusion.

Thus did the first Harveian lecturer, as we see from the veriest *editio princeps* possible of the first lectures, fulfil the precept to "make these dry bones live," to give the vivifying force of character, fancy, and originality to the general facts of anatomy. Since then two hundred and seventy-one years have run their course, and still the sacred fire of thought and genius burns in them undimmed by time.

There yet remains one part, perhaps the most important, of my prescribed task to be performed, and that is to draw a practical conclusion from the essentially physical and mechanical character of Harvey's great discovery. That he himself fully knew this has been already shown in his own words; it is also by his division of anatomy into three parts—philosophica, medica, and mechanica. Now at the present time investigation and research is abundantly carried on in the pathological, physiological, and therapeutical aspects of medicine, but the physical or mechanical side is somewhat neglected. For hundreds of ardent questioners of nature who are labouring with the microscope in the biological and bacteriological laboratories, those who attack medicine from its physical side may be counted on the fingers of one hand. Nor, indeed, are the written treatises on this subject abundant, in this country at least. The "Animal Mechanics," of the Rev. Dr. Haughton, of Trinity College, Dublin, is an exceptional work of great value, which has hardly received the attention it deserves from the medical profession, but it stands almost alone as the representative of its class. On the Continent, however, and in America the case is very different. The admirable "Medical Physics" of Professor Wundt, of Heidelberg, has been translated from the German into French, with valuable additions by Dr. Ferdinand Monayer, who regularly lectures on medical physics at the Lyons Faculty of Medicine, and affords a storehouse of information of the highest value to the medical practitioner. Dr. John C. Draper, Professor of Chemistry and Physics in the Medical Department of the University of New York, has also made a valuable contribution to the literature of this subject in his text-book of "Medical Physics," published the year before last. There is, indeed, a small but scanty manual by Dr. McGregor Robertson, the Muirhead Demonstrator of Physiology in the University of Glasgow, published in Cassell's Student's Series, but it is entirely unfit to compete with the two exhaustive treatises named before.

As with the bibliography, so with the teaching. With the exception of a course of lectures which the present speaker has delivered since 1871 in St. Thomas's Hospital, I am not aware of any systematic attempt in London to teach the medical student the vast mass of physical facts which underlie the daily practice of medicine. This College, however, forms an honourable exception, for it has on two occasions kindly given me the opportunity to bring before my brother physicians some few of what our Harvey terms *nova vel noviter inventa* respecting the physical basis of auscultation in the Croonian, and the electrical conditions of the human body in the Lumleian, lectures of a few years back. It is true that the University of London in its Preliminary Scientific Examination for the degree of Bachelor of Medicine requires students to satisfy their examiners in physics by means of a written paper. But this paper is the same as that set to Bachelors of Science not medical. It is a terrible stumblingblock to the rising medical generation; it bristles with what the late genial Professor De Morgan, himself a mathematician of the highest order, delighted to call mathematical conundrums. It is set by pure physicists, who know nothing, and probably care little, for the problems which interest us as medical men. It contributes a large percentage to the slaughter of innocent aspirants to the higher degrees in medicine, on which one of their most distinguished graduates, now Censor of this College, has feelingly and righteously commented. In the sixteen years during which I have carefully read the papers there set, I have never once seen a question directly or indirectly bearing on the physics of medicine. The fact is that the large, difficult, and somewhat heterogeneous branch of knowledge connoted by the word "physics" is rapidly splitting into several independent portions. There are now distinctly molecular, mathematical, industrial, and physiological physics. It is the last of these with which we are concerned. The third or industrial branch has been enormously developed of late by the technical colleges at Bristol, Manchester, the City guilds at Kensington, and elsewhere.

Digitized by Google

The mathematical branch is well cared for by the two old Universities of Oxford and Cambridge; but the physiological section has been hitherto hardly enough recognised by our teaching bodies. Surely an earnest student should be able somewhere to obtain information as to the natural laws on which the stethoscope, the microscope, the ophthalmoscope and the sphygmograph are founded, without having to wade through interminable problems on the C. G. S. system of units, or vortex theories of matter, or, chimæra of chimæras, the possibility and advantages of four-dimensional space.

It is to the promotion of this particular branch of study by means of experiment that it is this day my duty to exhort the College. An admirable opportunity exists, for in April of the present year the Committee of Delegates appointed by this College and the Royal College of Surgeons of England reported—"1. That it is desirable to utilise the vacant ground adjoining the Examination Hall for scientific purposes under the control and management of the two Colleges. 2. That the 'scientific purposes' be, in the first place, the investigation and exposition of such branches of science connected with medicine and surgery as the two Colleges may from time to time determine." The College has subsequently adopted the report.

Now I submit with the utmost respect, but with the greatest earnestness, to those here assembled that a course of physiological physics to be delivered in the new College of Science would be a real boon to all students of medicine, whether they had succeeded in obtaining their diploma or not. The human body is a mass or congeries of separate machines, susceptible of mechanical explanation; but, setting aside the heart and lungs already named, how many students have their attention specially drawn to Donders' and Landolt's optical researches on the eye and eyesight, or to Helmholtz's account of the mechanism of the ear? Such a course, moreover, would in no way clash with other courses given elsewhere on different branches of the same great subject, and it would eminently fulfil the exact purpose even to the very words of the great man whom we are to-day met to commemorate.

Remarks

ON THE

PSYCHOLOGY OF JOKING.

Delivered at the Medical Society of London, October 17th, 1887.

By J. HUGHLINGS JACKSON, M.D., F.R.S.,

PRESIDENT OF THE SOCIETY.

AFTER some introductory remarks, Dr. Hughlings Jackson said:—

I think punning does not receive enough attention. In spite of Dr. Johnson's well-known dictum, we should not despise punning. Sydney Smith says that it is the foundation of all wit. Supposing three degrees of evolution, I submit that punning is the least evolved system of joking, that wit is evolved out of punning, and that humour is evolved out of wit. Everybody has heard of Sydney Smith's remark—that it requires a surgical operation to get a joke into the head of a Scotchman. But he spoke without distinguishing. The Scotch have a great appreciation of those highly evolved jocosities displaying the humorous, although, no doubt, a scorn of simple, lowly evolved jocosities, such as plays on words. It is difficult to form a conception of a Scotch punster. Yet I have heard an Aberdonian, a physician of world-wide reputation, make a pun.

Punning is well worthy of the psychologist's attention. I seriously mean that the analysis of puns is a simple way of beginning the methodical analysis of the process of normal and abnormal mentation. This, I think, I can easily show. Vision is stereoscopic; in a sense it is slightly diplopic, for there are two dissimilar images, although there seems to be but one external object, as we call it. To borrow the ophthalmological term, we can say that mentation is "stereoscopic"; always subject-object, although we often speak of it as single ("states of consciousness," &c.). Just as there is visual diplopia, so there is "mental diplopia," or, as it is commonly called, "double consciousness." Now I come back to punning. We all have "mental diplopia" when hearing the answer to a riddle which depends on a pun:—"When is a little girl not a little girl?" Answer: "When she is a little horse" (hoarse)." The feeble amusement we have in the slightly morbid mental state thus induced is from the incongruous elements of a "mental diplopia." The word "hoarse" rouses in us the idea of a little girl who has taken cold, and the same sounding word "horse" rouses in us the idea of a well-known quadruped at the same time. We have the sensation of complete resemblance with the sense of vast difference. Here is, I submit, a caricature of the normal process of all mentation. The process of all thought is "stereoscopic" or "diplopic," being the tracing of relations of likeness and unlikeness.

To call punning a slightly morbid mental state may be taken as a small joke, but I do not think it very extravagant to describe it so; it certainly is not if it be a caricature of normal mentation. A miser has been defined as an amateur pauper; the habitual drunkard is certainly an amateur lunatic; and in the same style of speaking we may say that—well, we will say that punning is playing at being foolish; it is only morbid in that slender sense. The word "play" carries us forward in a slightly different direction. Jocosities of all degrees of evolution—(1) puns, (2) witticisms, and (3) humorous statements—are the "play of mind"; play in the sense in which the word has been used in the remark that the "æsthetic sentiments originate from the play impulse." A further definition of play as thus used is given in the following quotation from Spencer:—"The activities we call play are united with æsthetic activities by the trait that neither subserve, in any direct way, the processes conducive to life."[1] There would be a great intellectual advance—due, I presume, to internal evolution—when man began to value things for their beauty apart from their use, one sign of his having "got above" his mere animal self. For it showed that, over and above mind required for mere animal existence, he had some surplus mind for greater ends of life. So I contend that our race owes some respect to the first punster. For the dawn of a sense of the merely ridiculous, as in punning and the simplest jokes, shows the same thing as the dawn of æsthetic feeling—surplus mind, something over and above that required for getting food and for mere animal indulgence. All the more so if punning be that out of which wit and humour are evolved. It is not a good sign if a man be deficient in humour, unless he have compensation, as Wordsworth had, in a sense of the sublime, or in great artistic feeling, or in metaphysical subtlety. The man who has no sense of humour, who takes things to be literally as distinct as they superficially appear, does not see fundamental similarities in the midst of great superficial differences, overlooks the transitions between great contrasts. I do not mean *because* he has no sense of humour, but because he has not the surplus intellect which sense of humour implies. Humour, being the "play" of mind, is tracing deep, fanciful resemblances in things known to be very different. This is "playing" at generalisation, and is only a caricature of the same kind of process which made Goethe declare that a skull is a modified part of a vertebral column.

Now I am about—not really digressing from what I have just said—to say something which sounds very paradoxical: that persons who are deficient in appreciation of jocosities in their degrees of evolution, are in corresponding degrees deficiently realistic in their scientific conceptions. One would infer this *a priori*. Every child knows that a man born blind has no idea of light, but the educated adult knows, too, that the congenitally blind have no notion of darkness. And I think that observation confirms what *a priori* seems likely—that *pari passu* with the evolution of the sentiment of jocosity (playing at unreality) is the evolution of power of realistic scientific conception—from sense of the merely ridiculous with parallel realistic conception of simple things, up to sense of humour with parallel realistic conception of complex things. But we must be on our guard not to take commonplace realism about simple things to be realism when applied to very complex things. It seems at first glance more realistic to suppose that sourness is inherent in vinegar than that it is always a sensation in some percipient. But that the former hypothesis is very unrealistic is easily seen when we put such

[1] Prin. Psych. vol. ii., p. 627.

Digitized by Google

crude metaphysics in other words, the doctrine then is that part of the tester's own mind is outside himself. It is possible for the same person to be truly realistic in simple things, and to be intensely unrealistic in complex things. Thus, the really practical man, who may tell us that he despises metaphysics, may be crudely metaphysical when he deals with complex things—"explaining," for example, that a man comatose does not move because he has lost consciousness. Surely the truly realistic conception is that the comatose patient does not move any of his limbs from some physical disability—for, essentially the same reason that a hemiplegic man does not move his arm and leg.

I now go back to my small joke that punning is a slightly morbid mental state, a "mental diplopia," a caricature of the normal "diplopia" of healthy mentation. From this point I make the assertion that the "physiological insanity" of dreaming is diplopic—a caricature of that of waking mentation. A physician reads in the day of the strained relations of European States; in his dream at night he is called in consultation by Bismarck, and advises a course of the iodide of potassium (directions for the application of the remedy were not given). Clearly, there are here two very dissimilar mental states "pretending" to be stereoscopic; manifestly a seeming fusion of ideas of prescribing for a patient with ideas of the attitude of European States. I hope some time to be able to show that such diplopia has the same kind of mechanism as that of the pun—that the two elaborate dissimilar states are held together by two same, or similar, simple mental states. I go on to remark that in some people there are beliefs as incongruously diplopic as some states in dreams—diplopic in that way to other people, at any rate:—(1) Killing a rabid dog to prevent people already bitten by it going mad. (2) Imagining it to be possible to study what are called "diseases of the mind" methodically without distinguishing between the physical and the psychical. (3) A cleanly mother, from maternal solicitude, refraining from washing the top of her baby's head, lest it should come to have "water on the brain." (4) Imagining it to be possible to investigate complex subjects without the use of hypotheses; for instance, that Harvey could have made observations and experiments to *prove* the circulation of the blood without *supposing* beforehand that it did circulate. (5) Anointing a blade with healing salve to cure a wound inflicted by the blade.

Once more I go back to punning for a new start, trying to show again by very simple cases that punning is only a caricature of, and therefore for the psychologist a valuable experiment on, the process of normal mentation. I take first a case which is almost if not quite a pun, but one made unwittingly. What is called the inelegance of using the same word in one sentence, or in two consecutive sentences, causes mental diplopia. For even if each of the two words has the same dictionary meaning, we must bear in mind that a word loses something of that kind of meaning when forming part of a proposition, losing and taking meaning by and from its context. Hence the second time the word comes there is a faint revival of the idea it symbolised when used the first time, along with a vivid revival of other ideas it now symbolises; there is trivial confusion from slight mental diplopia, like that from an ill-understood pun. I now give a more striking example—one in which there is manifest diplopia without confusion.

A smell, say of roses, I now have makes me think of a room where I passed much of my time when a child. Here clearly is "mental diplopia," and the mechanism of it is quite similar to that of the pun, making allowance for caricature in the latter. For the true process is that the smell of roses, now having, develops what we call the same smell, but really another smell, that of roses once had, in the old room. The two scents, linked together, hold together two dissimilar mental states (1) present, now narrowed, surroundings, and (2) certain vague quasi-former surroundings. When the scent of hay, or the caw of rooks, rouses in us vague pleasurable feelings, the mechanism is of the same kind, but the process is more complex. To further insist on the fact that mentation is stereoscopic, with more or less manifest diplopia, I give an example of mentation which is exceedingly common. Whilst writing I suddenly think of York Minster. Here is manifest mental diplopia (1) narrowed consciousness of my present surroundings, with (2) cropping-up of consciousness of some quasi-former surroundings. Of course something, whether I can mentally seize it or not, in my present surroundings has developed a similar something associated with York surroundings.

Recapitulating, I say that the process of all thought is double, in degrees from a stereoscopic unity of subject and object to manifest diplopia (two objective states for one subject). The process of all thought is tracing relations of resemblance and difference, from simplest perception—to say what a thing is, is to say what it is like and unlike—up to most complex abstract reasoning. The formula of the caricature of the normal process of thought is the "pretence" of some resemblance between things vastly different,—from punning, where the pretended resemblances and real differences are of a simple order, up to humour, where both are highly compound. We have the "play" of mind in three degrees of evolution, three stages of increasingly complex incongruousnesses.

If I had time, I could, I think, show that this address on jokes is not itself merely one big poor joke, but that what has been said applies closely to the study of "mental symptoms" in serious diseases. I should begin the new stage of the inquiry with the quasi-healthy feeling of "reminiscence," clearly an element in a mental diplopia. For my task would be an endeavour to show that all morbid mental states are departures from normal (stereoscopic) mental states in particular ways—that, for example, the process of mentation in the maniac is but a caricature of stereoscopic and diplopic mentation in healthy people. Thus, the reminiscence, although it is almost pedantic to call it morbid, is really a link between perfectly normal and decidedly abnormal mentation. For reminiscence occurs in slight attacks of a certain variety of epilepsy, as do other voluminous mental states ("intellectual aura"): I call them all "dreamy states." These cases I should take next. There is clearly in them morbid mental diplopia, and yet this is traceably only a gross caricature of normal mental diplopia, being linked on to it by the reminiscence occurring in people we call healthy. And I think we may show that it has the same mechanism that puns have. Next taking these miniature and transient cases of insanity, and other cases commonly called insanity, I should try to show that the comparison of mentation with vision is of direct value. In the symptomatology of a patient who has paralysis of an ocular muscle there are many elements. There is morbid visual diplopia; in insanity there is morbid mental diplopia. The ophthalmologist's "true" and "false" images have their analogues in the "true" and "false" mental states in the cases of epilepsy mentioned. In the former, when the divergence of the eyes is slight, there is more visual confusion; in the latter, when the dissolution of the highest centres is shallow, there is more mental confusion. In the former, when the divergence is great, diplopia ceases (the patient, the ophthalmologist says, "neglects" the false image); in cases of epilepsy, upon deeper dissolution than that with which there is the "dreamy state," the actions are considerably coherent. The "erroneous projections" of the former have their clear analogues in the hallucinations of many cases of insanity. Believing that all diseases are to be looked on as flaws in different parts of one evolutionary system, I urge the "Comparative Study of Diseases of the Nervous System." I submit that, recognising the enormous difference between insanity and ocular paralysis, a profitable comparison and contrast may, nevertheless, be made, which will further a better knowledge of both. I do not mean simply that ocular paralysis may be taken as an illustration to simplify explanation of a case of insanity, but also that, both being examples of dissolution, the very same principles are displayed in each.

PARALYSIS OF THE ABDUCTORS OF THE VOCAL BANDS.

By GORDON HOLMES, M.D.,

PHYSICIAN TO THE MUNICIPAL THROAT AND EAR INFIRMARY, LONDON; CONSULTING PHYSICIAN TO THE SHEFFIELD EAR AND THROAT HOSPITAL.

History.—The theoretical conception of this disease, as far as literary records go, is first due to Galen,[1] who states that "if the muscles which open or shut the glottis are rendered immobile," both voice and respiration will suffer in proportion to the extent of the lesion. But his notions, based on no precise observation, are of the vaguest kind, the more especially as he considered that the inter-arytenoid and thyro-arytenoid muscles alone had the power of closing the glottis, all the others being in his view dilators. Hence

[1] De Locis Affectis, lib. iv., c. 6.

Digitized by Google

he would have connected the semeiology of this malady with paralysis of the lateral crico-arytenoid and crico-thyroid muscles, as well as with that of the posterior crico-arytenoids. Nevertheless, Galen was so much in advance of his own age and that which succeeded him that more than fifteen centuries elapsed before a pathologist arose to extend his conception, or even to appreciate its suggestiveness. About 1829 Albers[2] of Leipzig noticed cases of impeded respiration, which he called "laryngoplegia," and was inclined to set down to "paralysis of isolated muscles, especially the musculi dilatores glottidis." Such instances he conceived would arise in œdema of the glottis and croup (being then the chief cause of dyspnœa); also when tumours, such as aneurysm of the arch of the aorta, enlarged glands, &c., are so disposed as to press on the recurrent nerve; and, further, in case of ulceration or caries causing the muscles and cartilages to become separated. Before the introduction of the laryngoscope, however, this disease was of too recondite a nature to be recognised practically in clinical medicine. The first pathologist who gave it a really definite place in nosology was Gerhardt[3] of Jena, who about 1863 observed cases visually, and wrote an accurate description of the affection. "Should the posterior crico-arytenoid muscles on both sides," says he, "be alone affected, the strong contraction of their antagonists produces a glottis-narrowing continually progressive almost to closure. The inspiratory breath stream urges the vocal bands so near together that at the edges of the narrow chink remaining a loud friction sound exists (audible respiration). The voice is unaltered, whilst in recurrent paralysis it is essentially changed."[4] In these few sentences we have a picture of the disease almost clinically complete, and this short description was further elucidated by Gerhardt by remarks on the etiological and other collateral questions. In 1868 Mackenzie made this paralysis familiar to practitioners in this country by his essay on "Hoarseness and Loss of Voice," which exhibited for the first time a full view of laryngeal paralyses under an intelligible nomenclature. Finally, we may refer to Riegel's[5] extensive monograph on "Respiratory Paralysis," as marking the closing stage in the history of the malady, and bringing us up to the threshold of contemporary work in laryngology.

Semeiology.—Paralysis of the posterior crico-arytenoid muscles may be unilateral or bilateral. It is only in the latter case that the chief phenomena of the affection are developed.

Subjectively, as regards the larynx the leading symptoms relate to (*a*) respiration, but the (*b*) vocal condition also demands consideration.

a. In bilateral cases, the earliest—we may say, in fact, the only—trouble complained of is shortness of breath. The patient is always well aware from his own sensations that the obstacle to free breathing resides in the larynx. Thus he never, in uncomplicated cases, refers the obstruction to the chest, as happens in cardiac or pulmonary disease. This dyspnœa, as seen clinically, is usually progressive, and in the beginning, no doubt, as a rule, is almost imperceptible to the sufferer. In many instances, however, it halts at a certain point, and the patient may be but slightly incommoded, unless when muscular effort creates a demand for increased respiratory activity. In unilateral cases there is little or no interference with respiration, as the sound muscle by super-contraction can dilate the glottis sufficiently for all normal purposes.

b. With respect to voice, it is almost an antithetical distinction between bilateral and unilateral examples that the latter class present a vocal as exclusively as the former a respiratory obstacle. But the parallelism goes but a little way, because the vocal affection never attains any magnitude, whilst the dyspnœa may progress to a fatal result. Hoarseness, more or less decided, marks the unilateral paralysis; but the bilateral form, unless accompanied by a catarrh of the larynx, as not seldom happens, is free from this symptom. We have, of course, the phenomenon inseparable from all cases of respiratory derangement—viz., the impossibility of uttering a whole sentence in one breath, whence speech has a fragmentary broken character, with an [illegible] interval between every two or three words of [illegible] In addition, however, persons affected [illegible] by this paralysis speak so that the words have a peculiar short sharp ring, appearing to indicate that the vocal bands can only be held together firmly and steadily when assisted by the impulse of first approximation, although there may be no obvious affection of the adductors. No person in whom the malady is well developed can utter even a few words in a full and firm vocal tone. Hence, the bald statement usually found in text-books, that in the bilateral paralysis the voice is unaffected, appears to me to require a good deal of modification, and I consider there is a vocal characteristic that may often be recognised by the educated ear without further investigation as almost pathognomonic of this disease.

Objectively we have but one laryngoscopic sign proper to paralysis of the abductors of the vocal bands—namely, narrowing of the rima glottidis in its transverse diameter. This stenosis being brought about, as it is, by two distinct causes, also occurs in two different directions—namely, in lateral relationship, which is primary; and with respect to the linear centre of the glottis, which is secondary. At the earliest period of the malady in its bilateral form, before the development of any subjective phenomena, visual inspection could only notice that on full inspiration the glottis does not open to its widest extent, as happens in the normal condition; and during this act, when the paralysis has attained precisely its full development, the vocal bands cannot be drawn apart beyond the place they occupy when all the laryngeal muscles are at rest, —that is, the "cadaveric position," as Ziemssen calls the arrangement of the vocal bands as seen in the dead subject. But the narrowing, of course, does not necessarily stop here, for, in analogy with palsy in other parts, contraction of the unopposed adductors is likely to draw the vocal bands nearer and nearer, till, despite all efforts of the patient, the width of the glottis-slit is insufficient for the vital needs of expiration. Sonorous inspiration, often extremely loud during sleep, generally accompanies this stage. These results, however, are by no means constant, and many cases of much lower grade are lost sight of by the practitioner after having remained for many months in an apparently permanent unprogressive state. Thus the laryngoscopic picture is the exact complement of the subjective dyspnœa, and suggests nothing relative to vocal disturbance. In the unilateral paralysis the appearances, as confined to one side, are the same; and the glottis, especially during inspiration, is asymmetrical. We may also be able to observe that the affected vocal band is on a different level from that of the sound one, slanting from before backwards and downwards. The maximum of depression—which, however, is not likely to attain to 0·01 in.—is in the vicinity of the vocal process. The hoarseness, of course, directly arises from, and is proportionate to, this abnormality.

Pathogenesis.—In a majority of cases the exoteric etiology of this paralysis is very obscure. In some instances it undoubtedly originates in cold, especially when a subacute affection of a rheumatic character is produced in the cervical region.[6] It is also seen occasionally as the sequel of an acute attack of laryngitis, usually of a comparatively mild form.[7] Beyond these associations, clinical observation may recognise tumours disposed so as to press on the vagus or recurrent nerves, or evidences of brain disease, in which cases the paralysis is not likely to be pure, but will be more or less obviously complicated with other defects of motion or sensation in the larynx or elsewhere. Hence the pathogenesis of this malady is spread over a wide field, which can only be appropriately explored in the physiological laboratory or the post-mortem room, involving questions more proper for discussion in the next section. Mackenzie[8] thinks that

[4] This last statement, as we shall see later on, is only partially correct.

[5] Volkmann's Sammlung Klinische Vorträge, No. 95. Leipzig, 1870.

[6] A healthy young man, aged twenty-seven, applied to me for relief on account of a difficulty of breathing, which had lasted several days. He complained also of some stiffness and aching in the neck, but was otherwise well. The laryngoscope showed that the vocal bands did not separate for more than a quarter of an inch on deep inspiration. The larynx in general was quite healthy. Respiration was accompanied by a blowing sound. Hot inhalations were ordered, and in a week the patient returned almost cured.

[7] A strong, well-built man, aged forty, came under my care for dyspnœa, which had been increasing for about a week subsequent to an acute attack in the throat. Inspection of the larynx showed paralysis of the abductors of the vocal bands, which could not be separated beyond the cadaveric position. They had, moreover, a dull appearance, and were just perceptibly marked with a few pink spots. Generally the laryngeal mucous membrane was in a similar condition, and indicated the recent subsidence of a sharp attack of acute catarrhal laryngitis. Similar treatment to that in the last case was adopted, and the patient did not apply for further assistance.

[8] Diseases of the Throat and Nose, 1880, vol. i., p. 438, [illegible]

mechanical injury of the muscles during deglutition, owing to their exposed position, accounts for many cases. Such injury is supposed to be maintained and increased owing to the unceasing activity of the muscles, even when in a condition demanding temporary quietude. In proof he cites an instance from Ott,[9] in which the malady apparently arose from a piece of meat being impacted at the entrance of the œsophagus for twenty-four hours. Under ordinary circumstances such a conception of pathogenesis must appear far-fetched, nor can it be doubted that the activity of the muscles would be involuntarily modified were they in a tender state. Viewing, however, the rarity of cases of this disease (about one in two thousand of all laryngeal affections), it is possible to accept an equally rare etiology.

In the accompanying table of sixty cases of bilateral paralysis of the abductors of the vocal bands (nearly all published with sufficient detail) many points of its pathogenesis and practical relations are illustrated. Thus we can observe (*a*) that, though the disease may occur at any age, it is rare till after adult life; (*b*) that males are more frequently affected than females (two to one); (*c*) that the etiology is often obscure, and the line between neuropathic and myopathic examples cannot easily be drawn; (*d*) that the primary causes are extremely varied; (*e*) that many instances exist for years *in statu quo*; (*f*) that death from actual closure of the glottis is nearly always obviated by tracheotomy, &c.

Unilateral cases are probably much more common than bilateral, but owing to the slightness of their subjective symptoms must be constantly overlooked. On account of their slight semeiological importance in pure laryngology observers have not usually published the examples met with. Not requiring the concurrence of pressure on both vagi or recurrents, they remo are often associated with thoracic

TABLE OF SIXTY CASES OF BILATERAL PARALYSIS OF THE ABDUCTORS OF THE VOCAL BANDS.

Case.	Age.	Sex.	Neuropathic or myopathic.	Cause.	Known duration.	Result.	Authority.

60	42	,,	,,	Phthisis (enlarged glands)	(?)	(?)	Gouguenheim

Note.—By "cure" is meant that the abductors ultimately regained their functions; by "tracheotomy," that life was maintained only by means of constantly wearing a cannula. In all fatal cases, except Nos. 16, 33, 42, and 44, death was manifestly due to the primary disease. Individual references to all the cases need not be given here. Burow's table, the only one hitherto published (Berliner Klinische Wochenschrift, 1879), gives the above details in twenty-eight cases, and there many of them will be found. Others are in Mackenzie (Diseases of the Throat, 1880), and a few again in Semon (Berliner Klinische Wochenschrift, 1888), bringing the number up to forty-six. Fourteen then remain to be accounted for. Two of my own have already been described; respecting Case 3, there is nothing to add; in Case 4 there was hemiplegic paresis, with anæsthesia, and in Case 5 partial paralysis of the tongue. The rest will be found as follows:—Thirty-one in L'Union Médicale, No. 46, 1885; thirty-six in Annales des Maladies de l'Oreille, &c., May, 1886; forty-five in Wiener Medizinische Wochenschrift, No. 19, 1885; fifty-five in Dublin Medical Journal, 1879; fifty-six in Berliner Klinische Wochenschrift, No. 13, 1886; fifty-seven in British Medical Journal, 1885; fifty-eight in Riforma Medica, Nos. 84, 85, 1886; fifty-nine in Brain, Oct. 1885; sixty in Annales des Maladies de l'Oreille, &c., Jan. 1886.

Digitized by Google

aneurysm and lung tuberculosis than the bilateral form. Thus, out of twenty-three instances I find that nine arose from aneurysm and five from tubercle. Of these Semon[10] has collected sixteen cases, and seven have come under my notice. From a pathogenetic point of view the unilateral paralysis possesses a much greater importance than it does when regarded as a purely local lesion. Owing to the intimate relations of the recurrent nerves with the arteries within the chest, thoracic aneurysm or other tumours may produce this paralysis as a symptom of their presence long anterior to any other phenomenon clinically recognisable. Hence in suspicious chest cases examination of the larynx becomes a necessity, and *vice versâ*. The chest should be well explored on discovering the least grade of abductor paralysis.[11]

(To be concluded.)

SOME NOTES ON THE MINERAL SPRINGS OF AUVERGNE.[1]

BY M. AUSTIN BOYD,
PHYSICIAN TO THE MATER MISERICORDIÆ HOSPITAL, DUBLIN.

As the season has arrived when medical men are in the habit of suggesting for their patients additional therapeutic agents, in the shape of mineral waters, as a concomitant to change of air and scene, I thought a few notes on the many valuable springs of Auvergne, which I visited in the autumn of last year, would not be uninteresting to the Academy. Owing to the ease with which it can be reached from Paris by the Paris, Lyons, and Marseilles Railway, and the number and variety of the springs that exist in this volcanic district, Auvergne offers, in my opinion, one of the best localities on the Continent in which to choose a mineral water that will suit the therapeutic indications of most of the ordinary ailments physicians are called upon to treat. Situated in the midst of the most beautiful mountain scenery in France, and within easy reach of each other, these springs offer many attractions to the invalid, as well as to the daily increasing number of fashionable valetudinarians, who consider a course of mineral waters absolutely necessary in their annual existence. To one of the springs of this region—Royat, now so well known—I need not allude, as its character and therapeutic properties were so ably and graphically brought under notice by the late President of the College of Physicians, Dr. Cruise, in a paper read by him before the Academy of Medicine last year, that I could add nothing that he has not called attention to. There are other springs of this region to which it was his intention to allude in a future communication, and I trust he will not consider that it is in any spirit of anticipating him that the few remarks I have now to offer in connexion with them are made. The other springs to which I wish to allude are La Bourboule, Monte Dore, and Chatel Guyon.

La Bourboule.—This spring is now beginning to share with Royat an equal amount of popularity. The attention it is receiving at present from medical men in England, as a water particularly suited for the treatment of obstinate skin diseases, is calculated to make it ere long one of the most flourishing and fashionable, as it is at present one of the best, of the many springs of Southern France for such cases. Though for many years recommended by the Paris physicians for the value of its waters in such affections, it is only within the past seven or eight years, coinciding with the growth of [illegible] and the easier means of reaching it now by railway from Clermont—the capital of Auvergne,—that its value as a powerful arsenical spring has been recognised in these countries. The value of its waters is enhanced by its situation in the most mountainous part of Auvergne, being about 2600 feet above the sea level; and the invalids [illegible] go there can reach it in thirteen hours from [illegible]. Laquelle, which is the railway station for both La Bourboule and Monte Dore, is distant only about five miles from either place, and comfortable omnibuses convey visitors from the station to both of these places on the arrival of trains. The Bourboule springs have two sources, the source Perrière and the source Chaussy, both identical in chemical composition. The Perrière spring supplies 368 quarts per minute, at a temperature coming from the earth of 140° F.; and both springs, in addition to containing arsenic, with the chlorides and bicarbonates of the alkalies, contain large quantities of free carbonic acid, which renders them sparkling and limpid in appearance. The first chemical analysis made of the Bourboule waters in 1853 showed them as containing a large quantity of arsenic, a quantity equal to twenty-one drops of Fowler's solution in each quart of the water, the largest quantity contained in any mineral waters now known. Professor Berthelot, in giving his opinion of the origin of the arsenic in these springs, says: "The conclusion at which I have arrived is that the soluble arsenic contained in the Bourboule waters takes its origin from the interior of the earth; it is brought up in the waters through the fissures in the granite, and is not produced by their contact with disintegrated earth schistes and other materials situated above the granite. Soundings were also made through the granite formations of a depth of 250 ft. below the surface by M. Perrière, who found the pure arsenic waters at this depth. Nine-tenths of the solids contained in these waters are salts of soda, with ammonia, potash, and lithia, with lime, magnesia, alumina, and traces of iron; while the acids contained in them represent arsenious, hydrochloric, and carbonic. In 1856 M. Gonod discovered in the sediment of these waters the presence of iodine. Professor Gubler, when studying the composition of these waters, considered the salts contained in them corresponded to the salts found in the blood. They may be described as thermal, alkaline, arsenical, chlorinated bicarbonate, gaseous waters. Ten years ago La Bourboule was only a mountain village, with a few houses and one hotel; it is now a town of fine hotels (of which there are over fifty), with two parks, a theatre, and casino, and twelve or thirteen medical men, several of whom speak English. As indicating the rapid growth of the place, statistics show that in 1865 only 600 patients underwent the course of treatment, while in 1877 there were over 2800, and last year there were over 10,000 or 15,000 visitors. In 1875 the first respectable bathing establishment was built by a Frenchman, Dr. Chaussy, and a few years later, in 1879, a company purchased his interest in the place and built two other establishments, one of which, the Grand Établissement, is capable of accommodating over 300 bathers at a time, and is completely fitted up with all modern improvements. The waters for drinking are brought into the central hall of this establishment, and all round are situated bath-rooms, and halls for inhalation of the waters in a state of steam, and apparatus for pulverising it for throat and laryngeal cases, with rooms for ascending and local douches and wet and dry massage. The latter form of treatment is carried out on the most approved principles by skilled masseurs, so that any physician desiring such a mode of treatment for his patients can have it carried out here in perfection. Dr. Chaussy left a record of the cases treated by him at the spring for a period of over twenty-nine years, and nine-tenths of these cases were scrofula, rheumatism, and gout, especially the cutaneous manifestations of these diseases; special mention was also made of their beneficial effects in cases of chronic rheumatic arthritis. The springs are also held in high repute for the treatment of intermittent fevers, chronic coryza, hay fever, nasal and pharyngeal catarrh, strumous or tubercular joints, bronchial catarrh, asthma, and emphysema. Judging from my own observation of the cases I saw there, skin diseases, especially psoriasis, eczema, and lichen, seemed the more numerous, with numbers of cases of naso-pharyngeal catarrh, for whom the waters in the form of nasal douche and spray seemed admirably suited. I also noticed numbers of cases of suppurating cervical glands. As showing the beneficial effects of these waters on cases of all kinds of skin diseases, the medical men from the other watering places are in the habit of sending them to Bourboule to be cured, and my friend Dr. Brandt told me that many cases of psoriasis and chronic eczema that were not cured at Royat rapidly got well by an after course of Bourboule. The waters have generally to be taken cautiously at first, beginning with half a glass three times a day, increased to a glass, and their high temperature and saline taste are rather agreeable to some. If taken in too large a quantity they cause colic and diarrhœa, but most patients (even atonic dispeptics) bear them well, producing in them a feeling of warmth in the stomach, and

[illegible] 1883.
[illegible] in his papers
[illegible] Academy of [illegible], June 1st, 1887.

Digitized by Google

sharpening the appetite. The usual course of the baths and waters is twenty-one days, when saturation is supposed to be reached. As the altitude of Bourboule is high, the season does not begin until June, and it ends with September. The autumn months are generally considered the best, and medical men sending patients there should recommend a supply of warm clothing, as the evenings are often cold. The waters bear exportation well and keep a long time, and are, in my opinion, a most suitable form in which to administer arsenic, from the ease with which they can be assimilated by the most delicate stomachs. Either source will do, as they are both exported, and it is quite immaterial whether the brand indicates the source Perrière or Chaussy, as the waters are identical.

Monte Dore.—Monte Dore, which is four miles higher up in the same valley (the valley of the Dordogne River) than Bourboule, is reached in the same time from Paris. It occupies, however, a higher altitude than the latter, being about 4000 ft. above the sea level, and enjoys a cooler climate. Its waters are below those of La Bourboule in temperature, being 113° F. as they come from the earth. Like the Bourboule waters, they contain arsenic, but in smaller quantity and in combination with iron, which latter exists in the Bourboule water as the merest trace. They are therefore considered more tonic than the Bourboule waters, but are not, in my experience, so easily assimilated or drunk by the visitors in such quantity. The springs of Monte Dore were known to be three in number since the last century. They are now nine, and the united quantity of water they give is equal to that of Vichy. The Cæsar spring is the best known, and contains the largest quantity of free carbonic acid. The Raymond spring, which is the most ferruginous, is the one most generally drunk in conjunction with the Madeline, which contains much less iron. These three springs are the principal ones. The springs of Monte Dore are very ancient: they were known to the Romans, and the remains of their baths are still to be found in tolerable preservation where they were hewn out of the solid rock at the foot of which Monte Dore is built. The bathing establishment of Monte Dore consists of two parts: the establishment proper, and another building called the Vapour Establishment. In the first were found the remains of the Roman Piciua, where the waters came hot from the foot of the mountain. In 1877 two new halls were added to the pavilion—built in 1866—with thirty-six bathing closets, which originally contained only seven baths hollowed out of the rock. These new halls contain from fifty to sixty bath rooms, with a Piciua or bathing place, one of which is reserved for the poor *gratis*. The vapour establishment is, however, the great feature of Monte Dore. It was opened in 1852. On the ground floor are two galleries upon which sixteen vapour-douching closets open, eight on each side; between these two galleries here two pulverising-halls, one on either side for each sex, for the treatment of affections of the throat and nasopharynx. Each inhaling hall gives access to another smaller room where patients can breathe a less thick and hot vapour. Each patient before entering these halls is provided with a suitable waterproof dress worn over their ordinary clothing. A hundred patients at least can be accommodated in each inhalation hall. In 1877 the number of these inhalation halls was increased. The objects of inhaling the waters in a state of steam are to promote the absorption of their chemical constituents into the blood through the bronchial mucous membrane, and to medicate the bronchia and lungs locally should they be diseased. That the waters have a sedative action on the bronchial mucous membrane administered in this form, we cannot deny, and the doctors of Monte Dore ascribe it to the carbonic acid present in the waters. They illustrate the sedative and anæsthetic action of carbonic acid applied locally by getting patients with neuralgia of the face to hold the painful part over a tube placed over one of the springs so this gas escapes from it coming from the earth, and into which it is received, and they find after a few minutes complete relief from pain, while considerable anæsthesia of the parts is produced. They also use what is called a carbonic acid bath to relieve neuralgia or gouty pains occurring in the joints or muscles. Monte Dore enjoys a high reputation for the treatment of asthma, both of the spasmodic and bronchial kinds, and judging from its sedative action on the bronchial mucous membrane when applied in the form of steam inhalations, its good effects in the latter form are undoubted. In the spasmodic form of the disease, which we most commonly see often dependent on the presence of poisons in the blood, derived either from ptomaines or the unoxidised products of urea circulating in the blood, my own impression of the efficacy of the waters in this affection is that they play a very doubtful part in the cure, which is, I think, more due to the bracing mountain air and the better oxidation of the blood and better assimilation of food which takes place in such an altitude as a high altitude. Dyspepsia on any diet in such an altitude is consequently unknown, and quickly disappears after a short stay in Monte Dore. The Monte Dore doctors speak in glowing terms of the curative effects of the waters, when inhaled in the form of steam vapours, on ulcerating tubercular cavities in the lungs. My own impression is that change of air and the high altitude have more to do with any beneficial effects that are the outcome of their use than anything contained in the waters themselves. There is one feature in the manner of using these steam vapours which, judging from the recent light thrown on the pathology of phthisis, is certainly to be condemned—namely, crowding a number of cases of lung affections into a close moist atmosphere. We know such an atmosphere is just the very one in which the bacilli of phthisis is most at home, and there is every reason to suppose that mild or non-infected cases are likely to become the receptacles of the microbe, if they are not so already, by breathing such an infected atmosphere. I expressed such an opinion to one of the medical men there, and he agreed with me, and said the authorities of the place were taking steps to fit up separate inhalation rooms for each phthisical case, instead of having them, as at present, all crowded together. The medical men of Monte Dore do not consider the presence of hæmoptysis any contra-indication for the use of the waters, as they act, in their opinion, as astringents, both internally and topically; and they treat active hæmorrhage from the lungs by immersion of the feet in the rock-hewn baths where the water comes directly from the earth at its highest temperature, considering the revulsive action thus produced acts like the application of a Junod's boot. Besides cases of phthisis, most of those I saw at Monte Dore were cases of bronchitic asthma, emphysema, laryngeal affections, including tubercular ulceration of the larynx, laryngo-pharyngitis (clergyman's sore throat), rheumatism, uterine affections, palpebral conjunctivitis, and also chlorosis. The place enjoys a great reputation amongst singers for its effects on all laryngeal troubles, and, judging by the numbers who come there, they must derive benefit from it. The season at Monte Dore begins late (end of June), and is generally over by the beginning of September. The hotels are numerous and good, but the village itself is a dirty and an uninteresting one.

Chatel Guyon.—The third spa which I have mentioned, Chatel Guyon, is situated in a charming and picturesque valley of Auvergne, about six miles by road from Royat. Riom would be its railway station coming from Paris. Chatel Guyon is called by the French physicians the Kissingen of France, and its springs are very numerous, bubbling up in all directions over the place. Unlike Kissingen, its waters are hot, and not nearly so bitter or disagreeable to the taste. The amount of carbonic acid contained in the waters, and which escapes from the earth in every direction, makes the ground (especially in the large bathing establishments) quite hot under the feet. Their taste is slightly salt and acidulated, leaving a styptic after-taste. If drunk at the spring the saline taste is masked by the carbonic acid present, but if allowed to stand for some time the gas escapes and the saline taste reappears. The waters as analysed by Dr. Magnier, of the laboratory of the Paris School of Medicine, shows them as containing a large quantity of chloride of magnesium—thirty grains to the quart, to which their aperient action is due. They possess also very considerable diuretic properties. This analysis also shows them as containing, besides the chloride of magnesium, chloride of sodium, and bicarbonates of lime, soda, potash, and iron. When kept in a closed vessel these waters deposit their iron, with a small quantity of carbonate of lime and magnesia. For this reason the waters do not look well when exported if kept for any length of time. After taking a few glasses of these waters hot from the spring, there is a feeling of intestinal gurgling, followed by an abundant bilious discharge, with either copious diuresis or a free action of the skin. Although the peristaltic action of the bowels is rapid, it is neither preceded nor accompanied by griping or pain. The stomach feels no inconvenience from the use of these waters, except in cases where the drinkers take too large quantities at a time placed in the hour of the morning a glass or tumbler of the water, and then part passes down into the intestines and [illegible]

Digitized by Google

intervals. In some cases of obstinate constipation the laxative effect is not produced the first day, but when it is once produced it continues uninterruptedly without pain or inconvenience. The internal effect of these waters is considerably assisted by the action of the baths, which, from the large quantity of carbonic acid gas present in them, has a most exhilarating effect on the bather, producing a feeling of what the French call "bien-être," which none but an atonic dyspeptic can sufficiently appreciate. Owing to this effect, when used as baths, and taken internally, the waters are largely availed of by dyspeptics, and for many such cases these waters are superior to Royat, the waters of which, as is known, have no aperient action. The cases that seemed to me to frequent Chatel Guyon were those of obstinate constipation, and the medical men of the place speak in high terms of their effects in such cases, and that when once the habit of a daily evacuation is produced by their use the good effects continue after leaving the spring. I also noticed a number of people who came there to get cured of obesity, for the treatment of which the waters enjoy a considerable reputation; and Professor Gubler considers them especially useful in cases of Bright's disease and diabetes. The waters also occupy a high position in the opinion of gynæcologists as a remedy in endometritis, uterine catarrh, leucorrhœa, and dysmenorrhœa.

In concluding these remarks, I have only to add that those who visit Auvergne either for health, recreation, or amusement, will not come away disappointed. And the invalid who cannot find among its many mineral springs one to suit his particular ailment is not likely to find it elsewhere, but he cannot fail, at all events, to come away much impressed by its splendid scenery and improved by its bracing mountain air.

Dublin.

CASE OF

EPITHELIOMA OF THE TONGUE; REMOVAL OF LEFT HALF.

REMARKS ON THE OPERATION AND AFTER-TREATMENT.

BY LOCKHART STEPHENS.

MRS. H——, aged forty-two, first came under observation on Feb. 17th of this year for an ulcer on the left border of her tongue of five and a half months' duration, caused by a sharp point on the first lower molar of the left side. There was no history of malignant disease in the family or of syphilis in herself. The ulcer occupied the middle third of the left border of the tongue, extending slightly on to the dorsum, but more on to the under surface, and its character was that of epithelioma. No glandular enlargement. The rest of the tongue looked healthy. Early removal of the left half of the tongue was strongly advised. For a week before operation the mouth was well washed out six or eight times daily, and especially after taking food, with a saturated solution of boracic acid. On March 1st, chloroform being administered through the mouth by Mr. Palmer Stephens, laryngotomy was performed, and a silver tube tied in, through which the anæsthetic was then administered till the end of the operation. Assisted by Mr. Rory Fletcher, I proceeded to remove the left half of the tongue. The back of the pharynx was well plugged with two pads of sublimated wood-wool wadding, and the mouth well washed out with the boracic acid solution. Nearly the whole of the left half of the tongue was removed according to Mr. Whitehead's directions, with this exception, that instead of scissors a stout blunt director was used to tear through the muscles down to the lingual artery, which was ligatured before being divided. Except a few small vessels, which were readily stopped under sponge pressure, there was no bleeding beyond a general slight oozing. The mouth was again washed out with the boracic acid solution, and the pads removed from the pharynx. Although the anterior parts of the pads were saturated with blood, the posterior parts were quite clean, shewing that no blood had passed through or by them. The cut surface of the tongue was painted over with iodoform suspended in ether, whereby a uniform even coating of the powder was deposited. The laryngotomy tube was now removed, and the wound [illegible] with iodoform collodion. A small wood-wool pad was placed in the floor of the mouth, a strip of iodoform gauze laid over the teeth, and the mouth completely covered with an antiseptic pad made of sublimated wood-wool wadding in iodoform gauze. During the day, after the operation, some eight or ten of these pads were required, as all saliva and discharge passed into them before coming into contact with the air of the room. For the first four days the treatment consisted in the patient washing out her mouth three times daily with the boracic acid solution, iodoform being applied on each occasion. All nutriment was administered per rectum by means of enemata prepared with the extractum pancreatis and zymonised suppositories, which were given every four hours. The temperature never rose above normal, nor was there at any time the least odour to the mouth beyond that of the iodoform. On March 5th the patient drank half a pint of warm peptonised milk three times during the day in addition to the feeding per rectum, which was continued until the 11th, the diet consisting of milk, ox-tail soup, jellies, and beef-tea, all of which were peptonised. On the 11th she was able to go for a drive, and was gaining flesh. On the 17th the tongue had almost healed, and was feeling soft and natural. No glands could be felt. The patient was ordered to do very little talking for the next six weeks, and at most for only a few minutes at a time: to eat no solid food which would be likely to irritate mechanically, and to avoid hot and pungent articles of diet; also to take extract of malt with peptones three times daily after meals. On April 23rd it was noted that she had gained weight and strength since taking the malt.

Remarks.—That there is still much difference of opinion in the minds of surgeons as to the best method of operation and after-treatment of cases of epithelioma of the tongue is, I think, obvious from the different accounts to be found from time to time in the medical press and literature. The success of operators in Germany is in advance of those in our own country, if I am rightly informed, and this seems to be due mainly to their more elaborate application of antiseptic principles in operations on the tongue and jaws. Having had the opportunity of watching cases of removal of the whole or part of the tongue by nearly all the methods practised in this country, I believe that removal with scissors through the mouth is in most cases the best, in that it admits of antiseptic measures throughout, both as to drainage of the mouth and keeping the discharge aseptic. For at least a week before any operation on the tongue the patient should be instructed to wash out the mouth frequently, and especially after taking food, whether solid or liquid, with some antiseptic lotion, such as a saturated solution of boracic acid. The offending tooth or teeth should be extracted some three or four days before operation, in order that there may be no unnecessary oozing of blood after the tongue is removed. In the place of sponges I used pads of sublimated wood-wool padding enclosed in iodoform gauze, of various sizes, such as are largely used in most German hospitals, and found them most satisfactory. These pads can be made of any size, and are admirably adapted for making firm pressure on a bleeding point; they absorb well, and are readily seized by any kind of forceps or sponge-holder, and as any number of them can be ready to hand no time need be taken up in washing, as in the case of ordinary operation sponges. At first sight it seems difficult to apply an antiseptic dressing to a tongue case, but the difficulty is, I think, more apparent than real. After painting the tongue with the iodoform ether, the application of which causes a little smarting, not amounting to pain, and leaves a good even film over the wound, I well covered the mouth with a wood-wool pad, and kept it in position by elastic loops over the ears. By this means all saliva passed through a layer of absorbent antiseptic material before coming into contact with the external air. A number of these pads should be prepared for use, and a fresh one applied on each occasion of washing out the mouth or on its becoming saturated.

Mortality after operation.—In Mr. Butlin's work on "Diseases of the Tongue," I find up to Oct. 16th, 1886, Mr. Whitehead had removed the *entire* tongue in fifty-eight cases, with nine deaths, of which five were due to septic pneumonia. Mr. Morrant Baker at the same date had operated in "forty cases, with four deaths, of which three were due to septicæmia or septic pneumonia." Mr. Butlin, in discussing the causes of death after operation, says: "Although hæmorrhage cannot be made directly responsible for many deaths, it exercises a very large indirect influence on the results of operations. ..... The small quantity of blood which is lost is, in part at least, swallowed and in part passes down into the trachea and bronchi. It is liable

Digitized by Google

to undergo decomposition, and is probably a very important factor in the production of the earlier deaths from affection of the lungs and septic poisoning." Again, "the most common, and that to which attention cannot be too persistently directed, is affection of the lungs."

The fact that in nearly all these cases of lung affection the condition is due to septic changes is sufficient evidence that it is theoretically (and why not practically?) preventable. The possibility of *any* blood, no matter how small the amount, obtaining entrance to the air passages is of itself an element of danger and should be prevented. This in the hands of very skilful surgeons may be possible; but with many operators the safer plan would be to perform laryngotomy as a preliminary step, and to make sure that the pharynx was efficiently plugged before commencing the main operation. For this suggestion and others I am indebted to my friend Mr. Jacobson, of Guy's Hospital. So little inconvenience did the laryngotomy wound cause, that to this day, so far as I am aware, my patient does not know that she had a laryngotomy tube in for some twenty minutes. No additional risk is incurred by this precaution; but with the pharynx plugged a great source of danger is avoided. In connexion with the operation there is one point which cannot be too strongly insisted upon, and that is to stop each bleeding point as it is met with.

With regard to the after-treatment, the customary practice is, I believe, to omit feeding per rectum as soon as food can be taken by the mouth. With many cases this is not wise; for by the rectum a large amount of nutriment can be very efficiently introduced into the system. One reason for the early omission of rectal feeding has been the irritability of the bowel, which soon follows the use of ordinary nutrient enemata. This difficulty, formerly a real and practical one, has been overcome by the use of nutrient suppositories and peptonised enemata.

Emsworth, Hants.

CHLORIDE OF AMMONIUM IN THE TREATMENT OF HEPATIC DISEASE.

BY SURGEON-GENERAL W. STEWART, M.D.

THE method of treatment of hepatic disease by chloride of ammonium having been lately brought prominently forward in the columns of a contemporary in connexion with the controversy arising out of the discussion on Dr. Harley's paper on Hepatic Phlebotomy, read at the late Brighton meeting of the British Medical Association, I think the present an opportune moment to again revert to the subject, which I hold to be one of supreme interest and importance, seeing the great extent of our Eastern possessions, and the suffering and mortality from hepatic disease to which a large body of our troops and officials are exposed by service therein.

It is not my intention at present to touch on the surgical procedures that may be advisable in certain forms and stages of hepatic trouble. In a future paper I hope to say something on that point. Meanwhile I am tempted to quote the pertinent remarks made by Surgeon Thornton, in his highly interesting and suggestive paper read at the above meeting, that "we may include the liver in the domain of surgery, always, be it understood, when the physician says, 'I can do nothing more here.'" In his interesting letters on this subject in a contemporary,[1] my old friend and former brother officer, Brigade Surgeon W. Alexander, of Streatham, under the heading of "Chloride of Ammonium *versus* Exploratory Incisions in Inflammatory Diseases of the Liver," not only bears testimony to the great value of the chloride of ammonium treatment in his own hands, at home and in India and Burmah, but makes pointed allusion to the fact that "it is not generally known in this country." Surgeon-Major Ryan, too, in his able communication in the same journal,[2] bears similar testimony both as to its value and its inadequate appreciation by the profession at home.

Elsewhere,[3] I have ventured on a detailed explanation of the action of the chloride of ammonium, both special and general, in hepatic congestion. I have shown how, as long as that condition lasts, a local depletion is effected from the portal capillaries by each succeeding dose of the drug; and how, at the same time, by a species of auto-transfusion from the portal into the general circulation, the entire portal system, from its origin in the venous radicals in the intestinal mucous membrane, is freed from engorgement, and thus the liver is not only relieved from congestion and its functions restored, but the occurrence of dysentery, so apt to supervene in hepatic congestion, and particularly in tropical abscess, is prevented. The depletion of the congested abdominal viscera thus effected, unlike that by leeches or other local means, is not attended with depression or loss of vital fluid, a loss which in such cases is but ill borne.

Since the publication of my first paper on this subject in THE LANCET of May 7th, 1870, the chloride of ammonium treatment has been embodied in several of the leading text-books, both in this country and America. But I am sorry to say that, with the exception of Professor Aitken, not one of the English writers has given the details of the auxiliary treatment, diet, and management, without attention to which I have all along held its full success could not be attained. Murchison, however, adds his own testimony to "its great utility in hepatic congestion in this country as well as in India," and as the *general* effects of the chloride of ammonium, in hyperæmia of the liver, are summarily and tersely described by him, I cannot do better than reproduce them here. "In doses of twenty grains, two or three times daily, it induces free diaphoresis, increases the flow of urine, diminishes portal congestion, and relieves hepatic pain. It is believed also to stimulate the absorbents, especially those in the liver, and thus to effect the absorption of hepatic abscesses."[4]

Those who have seen the acute congestion of the liver in the East, as it reacts under the systematic use of the ammonium chloride, know how true all this is. But to those who have no experience of its effects in such cases, or who have only employed it in chronic cases, which have been ineffectually treated in India, till the liver has become chronically enlarged and demoralised, so to speak, so as to be much less amenable to the action of the remedy, the above statements may appear somewhat surprising. The latter class of cases, however, are those likely to be met with in invalids from abroad, whether in the private practice of the specialist or in the Royal Victoria Hospital, Netley. Indeed, the same may be said of the various convalescent depôts and general hospitals in India, into which similar cases make their way from up-country and out-stations after a variety of remedial measures have been employed and failed to effect a cure.[5]

In the limits of a paper of this kind it is impossible to do more than present a short summary of the auxiliary treatment, diet, and management of cases of hepatic congestion and tropical hepatitis, and of the rules to be observed in the administration of the ammonium chloride. But before doing so I must give a brief account of the *special* and characteristic symptoms produced by the drug in hyperæmia of the liver, which are peculiarly and directly referable to the liver and related parts, and for which it is necessary the doctor should be on the look-out, lest they be mistaken as evidences of the medicine disagreeing. They are, on the contrary, signs of its successful action—success signals, so to speak,—and as such should be carefully noted. The liver once freed from congestion, they, along with the *general* symptoms, are no longer manifested, and hence their occurrence after the administration of the drug in any given obscure case may be considered *diagnostic* of hepatic disease.[6]

The symptoms now to be described occur shortly after the medicine is taken, in from five minutes to half an hour. Sometimes a "shock" is felt, or as if "something gave way" in the side; at other times a succession of shocks is experienced in the hepatic region, accompanied or not by a

[4] For its use in the congestive stage of cirrhosis, see also Ringer's Handbook of Therapeutics.
[5] In this statement I also include cases in which, although the chloride of ammonium may have been used, it has not been systematically or persistently administered. That such cases are of very frequent occurrence, a long experience in charge of the European Detail Hospital at Madras, and afterwards as Deputy Surgeon-General of the district, has convinced me.
[6] For an account of the *general* symptoms produced by the drug in hyperæmia of the liver, which are equally characteristic and remarkably regular in the order of their occurrence, see my monograph and paper in THE LANCET, May 7th and 21st, 1870, above quoted.

Digitized by Google

pricking sensation ("pins-and-needles"), or as if cold water were trickling down the side; or the action is described as that of "a pulling" from one hypochondrium to the other, or from the margin of the right costal arch upwards and backwards as if through the liver; or a "clawing," "working," or "gnawing sensation" is spoken of as felt by the patient. When a single sharp shock is experienced in a debilitated, nervous, and susceptible subject, it is often severe; and I have known the patient to cry out in consequence, frightening the other patients in the ward, and being himself alarmed. Immediately afterwards, however, the severe hepatic pain vanished, and never again returned with its original severity; and with each succeeding dose a sensation of "pulling" only was felt in the hepatic region, till at length all sensible action ceased with the removal of the hepatic congestion, the case being one of simple enlargement of the liver. With the local actions excited in the liver and related parts—through reflex nervous action—when a full dose of the drug has been taken, motor impulses are similarly communicated to the muscles of the intestinal canal, causing its peristalsis to become more rapid and energetic, as evidenced by the "twisting" and other movements experienced in the situation of the duodenum, or all over the abdomen, and which at times are more sensibly felt in particular parts, in the situation of the umbilicus, or in the inguinal region. Simultaneously with or closely following the above phenomena, the abdominal muscles may be thrown into tonic contractions, which are perceptible at times to both sight and touch; and pulsatile movements are felt and are sometimes visible along the margins of the right inferior ribs. I have, in my monograph[7] above referred to, shown that all these phenomena are highly purposive, contributing, with other vital actions and processes brought about by the drug, to diminish portal congestion, restore the diseased liver to a healthy state, and afford relief to the entire system.

The following is a summary of the auxiliary treatment, diet, and management of congestion of the liver, and mode of administering the ammonium chloride:—

"Bearing in mind what has been said of the therapeutic effects of the drug in hyperæmia of the liver, and the indications to be drawn from the symptoms and pathology of the disease, the first thing to be done is to put the patient to bed, there to remain, in acute cases, during the whole course of the disease; in short, till the congestion, pain, and general and local distress and uneasiness shall have subsided, and that the patient may have no occasion to quit his bed, a bed-pan and urinal should always be at hand, as well as a trusty attendant to minister to his wants. By the recumbent position and the avoidance of all sudden and violent movements, mechanical rest and support are given to the enlarged, weighty, and oppressed or painful organ. The horizontal position, too, facilitates the auto-transfusion of the blood from the portal system, through the hepatic capillaries, into the general circulation, under the influence of our special remedy—a process which will be better understood now that the reader is in possession of the details of the local signs expressive of the effects produced by it: the excitation of the muscles of the intestinal canal to increased peristalsis, and those of the abdomen and thorax surrounding the liver to tonic contractions, by which muscular pressure is brought to bear on the radicals of the portal vein, and on the liver and gall-bladder, which not only hastens forward the entire portal stream, but may squeeze out of the liver some of the superfluous blood as well as free it and the gall-bladder from retained bile. By the increase of the functional activity of the liver, as well as the increased flow of blood to the skin, as a further result of its action, a *vis a fronte* is brought into play in aid of the *vis a tergo* above described, by which the equilibrium of the entire circulation is speedily restored. The free perspiration induced by the drug is also promoted and chills avoided by the rest and warmth of bed. I have shown elsewhere that it is to this latter stage of its operation that much of its value is due—the free diaphoresis favours sleep, while the nervous system generally is exhilarated and soothed, and the patient almost entirely relieved from all his distressing symptoms.

"It is equally important that the congested (or, it may be, inflamed) liver should enjoy, as far as possible, physiological rest. To this end, on no account must solid food be given to the patient, and wine, beer, or other alcoholic stimulants must be strictly prohibited. The diet must be of the least irritating character, and only small quantities of milk, beef-tea, or farinaceous articles should be taken at a time. Barley water may be taken freely as a drink. If there be diarrhœa, the patient passing frequent loose bilious or dark-coloured motions, a pill composed of two grains of mercury and three grains of Dover's powder, repeated every two hours till four or five have been taken, will be found the most effectual means of checking it without the risk of setting up gastro-intestinal irritation. Looseness of the bowels, however, does not contra-indicate the use of the chloride of ammonium—indeed, it is in itself the best remedy in cases of diarrhœa associated with hepatic congestion. The only condition which contra-indicates the immediate use of the drug in acute cases is the existence of a combined hot and dry state of the skin with pyrexia. Under such circumstances its use should be preceded by a few small and frequently repeated doses of solution of acetate of ammonia, till the skin is rendered moist and perspirable. Pyrexia being absent—or, if present, the skin being soft and perspirable,—the chloride should be at once commenced and persistently administered in doses of twenty grains twice or thrice daily, with strict attention to the rules above laid down as to diet, rest in bed, &c., till it no longer produces sensible effects, or till all local uneasiness, hepatic pain, and tenderness have subsided. Fomentations or hot bran-bags applied to the seat of pain in the side will be of use in aiding determination to the skin generally, as well as by their local soothing effects.

The following case illustrates the beneficial action of chloride of ammonium, as well as the characteristic and *special* symptoms following its administration in the various forms of liver congestion met with in India and other tropical countries. But congestion of the liver and functional derangements are of more frequent occurrance at home than is generally imagined, and our special remedy has been found to be of great service in this country, not only in congestion, but what is commonly known as "torpor of the liver", and functional derangements, attended by lithæmia (Murchison), associated with congestion of the liver, want of sleep, and depression of spirits, in all of which cases the drug is pre-eminently useful.[8]

H. C—— was admitted into the hospital, Secunderabad, on Nov. 9th, 1880, suffering from simple enlargement of the liver, with much pain and tenderness in the right hypochondriac and epigastric regions. He stated that for about six weeks prior to admission he felt more or less uneasy in the right side. This feeling was not one of pain, but gradually prevented him lying on either side, owing to a sensation of weight and increased uneasiness in the hepatic region; and this feeling was increased by lying on the left side. For about three days before reporting himself sick he experienced a dragging pain in the right side. For some time previously to admission he felt a bitter taste in his mouth on rising in the morning. On admission the left lobe of the liver was found to descend to within two inches of the umbilicus, and hepatic dulness existed in the right mammary line to within two inches of the crest of the ilium. There was exquisite tenderness all over the hepatic region on gentle pressure. Decubitus dorsal; bowels regular; temperature normal; pulse 74. Chloride of ammonium (twenty grains) was given thrice daily, fomentations were applied to the side, and the patient ordered not to quit or move suddenly in bed.—Nov. 10th: Medicine acted characteristically, producing symptoms which the patient described as follows:—A short time after taking the medicine a sensation of "pins-and-needles" starts from the middle line in the lumbar region, and travels slowly up along the margins of the ribs of the right costal arch, and on reaching a point corresponding to the right mammary line remains stationary for a while, and is then followed by a "darting" at the above points, when the pain subsides, and he remains relieved for a considerable period.—12th: Yesterday evening the patient sent for the apothecary on duty, complaining of severe darting pain situated at the margin of the ribs in the right mammary line. He was hysterical and sobbing. He said the pain came on a short time after the last dose of the medicine—about half an hour previously. The pain increasing in intensity, he either lifted or "felt himself lifted up," as he expressed it, and immediately

[7] See also the Madras Monthly Journal of Medical Science for February and March, 1872.

Digitized by Google

afterwards felt another dart, worse than before, and something seemed to slip up, and he felt relieved and went to sleep. The lower margin of the liver has receded an inch and a half higher up from the point previously noted, and the pain and tenderness are much relieved. Continue treatment.—14th: The liver has receded in the right mammary line to its normal position under the ribs, and the left lobe is now nearly of normal dimensions. Temperature normal; pulse 74; bowels regular. Pain and tenderness over the hepatic region much diminished, and medicine still acts characteristically, but its action is not so marked. Continue treatment, and low diet as before.—16th: Pain and tenderness gone. Liver enlargement entirely reduced. The local action of the medicine is not now so marked. The sensation of "pins-and-needles," commencing in the centre of the lumbar region, reaches only to a point an inch from the right mammary line in the course of the costal arch. Continue treatment.—20th: Doing well. Medicine produces no sensible action. No pain or tenderness anywhere, on pressure or movement. Countenance clear and bright. Colour returning to face. Continue treatment.—26th: Doing well; chloroide of ammonium (ten grains) given thrice daily. To have chicken diet. Allowed up for half an hour daily.—30th: Discharged from hospital quite well, but a little weak. To attend hospital as a convalescent for a few days.

The above case furnishes a good example of that state of disordered liver—well described by Annesley more than seventy years ago—so common in the stations of the Madras Presidency, which, commencing in imperfect discharge of the liver functions, when long continued terminates in congestion of the portal veins and engorgement of the ducts conveying the bile from the secretory structure of the organ. If this stage or form of disease be neglected, or only partially recovered from, it will terminate in a longer or shorter time, according to circumstances, in inflammatory action of a subacute kind with marked tendency to suppuration, in a limited portion or portions of the parenchyma. But in tropical hepatitis, no matter what may be the stage, the ammonium chloride is still the one special remedy for the specific disease, as I have fully shown, and amply confirmed by the statistics and cases published in my monograph. In the *Indian Medical Gazette* of July 1st, 1881, will be found further statistics on the subject; but as this paper is, I fear, already rather long, I must reserve what I have to say on that point for a future occasion.

Ilymington, Hants.

TWO CASES OF EMPYEMA.

By JAMES W. FRASER, M.D. C.M. EDIN., M.R.C.S. ENG.

The following almost parallel cases of empyema illustrate the well-known superiority of the treatment by early incision and dry antiseptic dressing.

CASE 1.—Ellen J. C——, aged eight years, was first seen on April 15th, 1886, in an acute febrile condition, depending apparently on the inhalation of sewer gas. This was followed by left-sided pleurisy with effusion, which increased in spite of treatment until May 13th, when the heart was found to be beating entirely to the right side of the sternum. Aspiration was therefore employed on that date, and the effusion, which was serous, was removed, the heart returning to its proper position, or nearly so. The fluid, however, reaccumulated; but the aspiration had had such a demoralising effect on the parents, and the child herself was so unmanageable, that when further operative interference was declined it was not strongly urged. The effusion increased, becoming purulent, and pointed in the mid-axillary line in the sixth interspace, the opening taking place spontaneously on July 16th. Preparations for the discharge were made by washing the skin with carbolic lotion and covering the side with a thick layer of corrosive sublimate wood-wool wadding. No further antiseptic precautions, beyond the insertion of a drainage tube and in the later weeks of the treatment washing out the side with weak iodine water, were taken, but the discharge never became offensively septic; still it was so abundant as to require the dressings to be changed daily until Aug. 10th. It was not until September 11th that the child could be sent from home, even then with a small discharging sinus. She has since been seen, and the chest appears equally resonant on both sides, nor is there any lateral curvature.

CASE 2.—Charles P——, aged nine years, had a very slight attack of scarlet fever, the rash appearing on March 31st, 1887. He progressed favourably until early in April, when he apparently caught cold, and the signs of left-sided pleurisy were discovered on April 13th. The effusion increased rapidly, and the apex beat of the heart on the 15th was to be felt to the right of the ensiform cartilage. The aspirator was used on that day, and the effusion was found to be purulent. The fluid reaccumulated, and the boy passed into a hectic condition, with diarrhœa and an evening temperature of 102·5°. Though this patient was fully as unmanageable as the former, the parents were more reasonable, and their consent to opening the side was readily obtained. This was therefore done on the 21st, cocaine being used as the anæsthetic, and full antiseptic precautions taken. The carbolic spray was used, and when the natural flow of the matter had ceased, a further quantity was removed by the method of perflation described by Dr. Ewart in THE LANCET (vol. ii. 1886, p. 226). The incision was in the sixth interspace behind the posterior axillary line. A large-sized drainage tube was introduced, and a dry dressing of corrosive sublimate wood wool applied. The dressing was only changed when the discharge came through, which for the first week was night and morning. Signs of carbolism were seen on the 24th, depending partly on the liberal use of the spray and partly on the carbolic lotion used to purify the air used in the perflation. Tincture of iodine was substituted for the latter, and the dressings were performed as rapidly as possible and the carbolism disappeared. The temperature fell to normal on the day after the operation, and all went on well until May 2nd, when the hectic fever and diarrhœa recurred. These appeared to be caused by the dressings blocking the mouth of the tube, for when this was remedied the use of aromatic sulphuric acid and tincture of bark soon reduced the temperature and controlled the bowels. On May 20th the tube was found to have been pushed out, and the only sign of the disease was a sinus less than half an inch deep. The boy is now perfectly well and the lung is evidently well expanded, though the left side is still less resonant than it should be.

From the opening of the abscess to the time of full recovery in the first case was seven weeks, from the incision to the full recovery in the second four weeks; a clear saving of three weeks by antiseptic incision and dry treatment, to say nothing of the saving of all the time occupied in the natural passage of the pus to the surface in the former. Two minims of a 10 per cent. solution of cocaine was the anæsthetic used in the second case, and the boy, though he roared lustily all the time, confessed afterwards that he never felt the knife. In order, if possible, to obtain quietness by removing the pain even of the prick of the subcutaneous needle, a 5 per cent. ointment of cocaine in lanoline was rubbed into the side, but only appeared to deaden the pain; possibly a 10 per cent. ointment would have been more successful. The use of tincture of iodine instead of carbolic lotion in the wash bottle of the perflation apparatus is also important by reducing the danger of carbolism.

HOSPITAL FOR SICK CHILDREN.

TWO CASES OF CALCULUS; OPERATION; REMARKS.

(Under the care of Mr. JOHN H. MORGAN.)

As is well known, a very great revulsion has taken place of late years in the treatment of calculus at all ages, and the more general application of lithotrity, with complete evacuation, has proved so satisfactory in its results in adults that surgeons are turning their attention to the question of its applicability in the case of children. Whatever the verdict that may be arrived at in future, cases will arise in

Digitized by Google

which lithotomy must be the operation preferred, and then comes the question as to the choice of the old and well-tried lateral operation or the more recently advocated one through the abdominal parietes. The following two cases (for the notes of which we are indebted to Dr. Penrose) may serve to illustrate the question of choice, and also to emphasise the satisfactory results obtained by either operation in suitable cases.

CASE 1. *Embedded calculus; supra-pubic lithotomy; recovery.*—E. H——, aged sixteen months, a weakly-looking boy, with marked evidences of rickets, was brought to the hospital on account of difficulty in passing urine. The mother had noticed this three months previously, when she also observed that the straining gave rise to prolapsus ani. A doctor had attended the child during this period on account of wasting and diarrhœa. A fortnight before admission the boy did not pass any urine from 8 P.M. one evening until 9 A.M. the following morning, during which time he was in great pain, screaming violently, and straining. This was relieved by a doctor who passed a catheter, at the end of which, on its withdrawal, a small piece of hard substance, about the size of a pea, was brought away, and another similar piece was passed by the child a little later; this was whitish and hard, and crumbled away when exposed. After this he was better, but screamed when passing urine. No blood was observed in the urine. He was sounded under the influence of chloroform, and a stone detected, which appeared to be of considerable size, but not readily movable in the bladder. Here was a set of circumstances in which lithotrity could not be entertained; the large size of the stone, its immobility, together with the small calibre of the urethra and the very feeble condition of the child, all tended to put such a suggestion out of court. Again, the very narrow orifice of the pelvis, which was deformed by rickets, did not promise success to the lateral operation if performed, especially considering the presumed size of the calculus. It was accordingly decided to perform the suprapubic operation, and this was done according to the method now in vogue on June 11th, the bladder having been emptied and then injected with boracic solution, and the rectum distended by an indiarubber cone. Upon opening the bladder, which was devoid of all peri-visceral fat, the left forefinger was inserted, and the stone was felt lying in a sacculus in the region of the trigone below and between the orifices of the ureters, surrounded and overlapped by the mucous membrane of the bladder to such an extent that it became necessary to raise the calculus from below by the assistance of the right forefinger inserted into the rectum. By this means it was easily freed and pushed into the cavity of the bladder, where it was grasped and removed by a pair of forceps. The stone was conical in shape, the base which lay uppermost being nearly flat, whilst the cone lay deeply embedded in a sac of mucous membrane. It was composed of uric acid, with a crust of phosphatic material, and measured seven-eighths of an inch from base to apex, the weight being fifty-three grains. No sutures were applied to the bladder wall, but a small piece of catheter was inserted and allowed to project from the lower part of the abdominal wound, which was brought together above this point by three sutures of catgut. Next morning a small shell of phosphatic covering of the stone was found under the protective. The temperature was normal, and some urine was passed per urethram, as happened also upon the following day. On the third day following the operation almost all the urine passed by the proper channel, and from this date until his discharge at the end of a fortnight there was no interruption to perfect recovery.

CASE 2. *Lithotrity in a boy aged three years and three months; recovery.*—F. B——, who had been suckled for a year, was noticed to have pain in passing his urine in February last, after a severe attack of bronchitis. In the following May he was circumcised at another hospital, but was taken to Great Ormond-street, on account of the frequency with which he passed urine. The passing of motions caused him to cry, and the stools contained slime and worms. He occasionally woke at night to pass urine. He was admitted and sounded, and a fair-sized stone was detected. On July 13th, the patient being under the influence of chloroform, the meatus having been slit to a small extent, Mr. Morgan introduced one of Weiss's lithotrites, No. 7 English scale, and, after breaking up the calculus, washed out the bladder with the evacuator described by him in THE LANCET (Sept. 2nd, 1882), and using a tube of the calibre of a No. 8 catheter. The lithotrite was introduced three times, the third time for the purpose of sounding only, and the bladder was washed out four times. No further fragments being found, the child was sent back to bed. No difficulty whatever was found in introducing either the lithotrite or the tube of the evacuator once the meatus had been passed. The fragments of stone collected weighed forty-one grains and a half. For the next two days the boy suffered no pain; the urine was passed naturally and without pain, and on examination was found to be acid, with a small amount of albumen, the sediment containing pus and epithelium cells. On the third day two small fragments of stone were passed with the urine, which weighed about one grain. On the sixth day there was much pain in micturating, and frequent desire to pass urine. This soon subsided under treatment, but no more fragments were passed. Ten days after the operation the patient was sounded carefully under an anæsthetic, and the bladder washed out with warm water. No more fragments of stone were found, and on July 25th he was discharged from the hospital, eleven days after the operation, and he has since that time remained perfectly well.

Remarks by Mr. MORGAN.—This case is interesting from being the first in which, at the Hospital for Sick Children, a boy of such early age has undergone the operation of lithotrity, and the ease of its performance and the successful result point to its adoption in similar well-suited cases. At the same time, the case which precedes it shows that lithotomy in some form cannot be abandoned in certain circumstances, though how far the supra-pubic will supplant the older lateral operation still remains to be seen.

GREAT NORTHERN CENTRAL HOSPITAL.

DISEASE OF THE HIP-JOINT; EXCISION OF THE HEAD OF THE FEMUR; SUBSEQUENT REMOVAL OF THE GREAT TROCHANTER; GOOD RESULT.

(Under the care of Mr. W. SPENCER WATSON.)

WE are indebted for the notes of the case to Mr. Strugnell, house-surgeon.

Lavinia D——, aged seventeen years, had suffered from the usual symptoms of hip-joint disease on the left side since the age of five years. Successive abscesses had formed, and the joint had become painful, with nocturnal startings, sleeplessness, and hectic. There was no movement of the joint, and a shortening of an inch. Weight extension and rest were tried from Dec. 20th, 1884 (the date of admission) to May 20th, 1885. At first the relief experienced by the extension was very great, but the pain and all the other symptoms were soon as great as ever, and on May 20th the head of the left femur was excised, leaving the trochanter and shaft untouched. The head was entirely denuded of cartilage, and presented an eroded and wasted surface; the cartilage of the acetabulum was ulcerated, but, there being bare bone, it was not scraped or otherwise interfered with. The wound was dressed antiseptically, and both lower limbs put up into a Bryant's splint, which, however, was exchanged on May 24th for an interrupted Liston's splint, with weight extension. On June 1st the wound had healed, with the exception of a small sinus. There were no other symptoms of note, and on July 18th a Thomas's splint was applied, and on Aug. 22nd the girl was allowed to get up and go about on crutches. She was discharged on Sept. 19th, there being still a slight discharge from a small sinus, but the limb was movable at the hip to the extent of 30° from the perpendicular axis.

In November the girl was readmitted and complained of severe pain. The still discharging sinus was reopened and the cavity of the joint explored with the finger. No bare bone was felt, but the great trochanter was found to be drawn up with great force over the edge of the acetabulum by the muscles attached to it; and it was thought that this continual muscular action was the cause of the constant pain complained of by the patient. On Feb. 13th, 1886, the wound was freely opened and the great trochanter sawn off. The small trochanter and the muscles attached to it were not interfered with. The progress of the case after this last operation was satisfactory but slow, and with intercurrent attacks of severe pain and rise of temperature; but in the autumn of 1886 the sinuses had all healed and left a movable sound joint, with very moderate amount of shortening.

On March 20th the patient came to the hospital on

Digitized by Google

crutches, looking much stronger and better. She was now able to walk for a few steps without crutches.

May 4th.—Has been in hospital again with a small superficial abscess in the inner aspect of the thigh, which was opened and has now healed. The condition of the joint is still quite satisfactory.

Remarks.—The operation of removing the head of the bone without the trochanters seemed to be likely to succeed in this case, as the disease was strictly confined to the head and acetabulum. The pain, however, due to the spasmodic action of the muscles on the great trochanter was so great that it was necessary, after all, to remove this process of bone. The operation being a larger one, and exposing the cancelli of the shaft, is probably a more dangerous one, and it would be well if we could by some means avoid it without exposing the patient to the risk of the pain due to muscular action afterwards. It would be desirable to divide the muscles attached to the trochanter only, and leave the bone untouched. The difficulties of the case were aggravated by the extremely irritable and hysterical temperament of the patient, and the want of sleep associated with this temperament. Mr. W. Adams' osteotomy saw was used for the purpose of removing the head of the bone in the first operation, and the difficulties of the section of the neck would have been insuperable without this instrument.

BRISTOL GENERAL HOSPITAL.

A CASE OF SUPRA-PUBIC LITHOTOMY, AND ONE OF SUPRA-VAGINAL HYSTERECTOMY.

(Under the care of Mr. NELSON DOBSON.)

Supra-pubic lithotomy.—A man, aged fifty-one, looking older than his age, was operated on by the supra-pubic method on September 3rd. The case is interesting from several circumstances, but chiefly because he had been twice operated upon by Mr. Dobson in six months for stone in the bladder; on the first occasion by the lateral method, and on the second by Peterson's method. The patient was very intelligent, and with his experience of both operations he gave a preference to the supra-pubic as having given him more freedom from discomfort after the operation; but unfortunately, as the rectum was wounded in the lateral operation, he experienced more uneasiness than is usual after this operation, and therefore his comparisons between the two operations to which he was subjected are scarcely fair tests of their relative merits.

This patient first came under Mr. Dobson's care in March, 1886. He was a highly nervous, sensitive man; had had for a long period difficulty in passing urine, pain (very acute) accompanying and following micturition. He said that he had a stricture at the orifice of the urethra, for which he had lately been under the care of two surgeons. He was told that he possibly had stone in addition to his other troubles. Chloroform was given, and a narrow, very unyielding stricture of the urethra, commencing at the orifice and extending down the urethra for an inch, was found; also, on sounding, a stone, which appeared to be of fair size, and gave the impression of being phosphatic. It was attempted to dilate his urethra with a view to crushing; but it would not dilate beyond about No. 5 sound; therefore, as his sufferings were very considerable, on March 5th, having introduced a No. 5 staff, lateral lithotomy was performed. On introducing the finger, Mr. Dobson felt a round smooth stone about the size of a large walnut. The forceps were passed and the stone grasped very lightly, and the operator prepared to extract, when the forceps appeared suddenly to have lost grasp of the stone. Search was again made for a few moments for the stone with the forceps, but, failing to find it, the finger was introduced and discovered the bladder strewn with a crumbled phosphatic stone. The débris was removed by the scoop and frequent washings. The weight of the recovered fragments was 125 gr., but as much again was lost in the washings. There was no evidence of wound of the rectum; but on March 8th, an aperient having been given and the bowels moved, fæces were noticed in the perineal wound. This wound was examined with the finger, and an opening found in the rectum. On the 10th the perineal and rectal wounds were laid into one by cutting through the sphincter. On April 27th all had healed except a small rectal fistula; and by June 1st the fistula had quite healed.

On Sept. 3rd the man came again to the hospital with the old symptoms of cystitis and pain stricture still tight, but improved; the pain and constitutional disturbance severe. On sounding, a calculus was found. Having regard to the condition of his urethra at the meatus, and low down in the perineum, Mr. Dobson decided to perform supra-pubic lithotomy; this was done on Sept. 3rd, and a small irregular phosphatic calculus removed. The rectum was distended by means of Peterson's bag with 13½ oz. of water, and the bladder with 12 oz. of warm boracic acid lotion. There were no difficulties of any kind. A catheter was placed in the bladder, and a large drainage tube in the wound. Next day the drainage tube was removed, and on the 8th the catheter was also permanently removed. On the 27th the wound was nearly, but not quite, healed. In a few days later he left the hospital quite well, and has not since been seen. He complained very little of the discomfort of the second operation, but was somewhat envious of a patient in a bed opposite to him, from whom several fragments of stone had been removed by the median operation thirteen days later, and who was quite well before him; this last patient had been subjected to litholapaxy by Mr. Dobson and others on more than one occasion, who had felt compelled to cut him in consequence of the evacuator being broken just as he was about to crush him once more.

Remarks by Mr. DOBSON.—The advantage of the supra-pubic operation in this case was greater than usual, because it enabled me to evercome all the urethral difficulties, and to be quite sure by inspection that I had thoroughly emptied the bladder. I would also lay stress on the importance of dividing the sphincter in all cases of accidental wound of the rectum in the lateral operation. I have done the lateral operation many times, and have, so far as I know, avoided this accident in all my previous cases. I believe when this accident does occur the proper treatment is as I have indicated, notwithstanding the divergence of opinion among the authorities.

Supra-vaginal hysterectomy for uterine myoma.—J. S——, aged forty-seven, a slim, delicate, highly neurotic single woman, was first seen in July, 1886. She had been much overworked as a governess, and in failing health for some months. She had been completely confined to bed for three weeks. She was so nervous and sensitive that only the most superficial examination could be made. The walls of the abdomen were œdematous, and the legs very œdematous from the feet to the groins. There was no albumen in the urine, the temperature was normal, her pulse feeble and rapid, and she was much emaciated. A large solid tumour occupied the centre and left side of the abdomen, stretching from the pelvis to the diaphragm, smooth, and apparently movable as far as her tenderness would allow. Vaginal examination only indicated normal conditions so far as the finger could reach; the uterine sound was never used. There was no evidence of fluid in the abdomen, nothing to be noticed on auscultation; but a distinct pulsation was communicated to the hand laid gently on the abdomen, which pulsation was transmitted from the aorta; the percussion notes those of a solid (probably uterine tumour). Mr. Dobson gave a decided opinion against operation, thinking from her general condition she had only a very short time to live, and also that the tumour was malignant. When seen again in December her condition was much the same as before, though somewhat improved; she had now for more than seven months been completely confined to bed, and was anxious to have her tumour, which at this time was thought to be a myoma of the uterus, removed. This was done at the hospital on Jan. 17th, 1887. She still continued to menstruate, had just passed her period, and never suffered excess or any irregularities. Chloroform being administered, a four-inch incision was made and the nature of the tumour ascertained. The incision was then carried rapidly through and beyond the umbilicus; the uterus turned out with its tumour; and, as the right broad ligament was very expanded and difficult to surround with the serre-nœud, it was ligatured in two parts, but the ligatures when applied shrunk the broad ligament sufficiently to enable the serre-nœud to be passed behind, and this was rendered more easy as the left ligament was of abnormal size. Having passed the pin through the centre of the pedicle, and having also dissected off from the front of the tumour the bladder, which was very closely connected at this point, a pedicle was left as thick as the wrist. The pelvis was then packed with sponges, and the mass cut off above the central line and closely trimmed. About a pound of blood escaped from the tumour, but none found its way into the abdomen. The tumour, which was mostly intramural and growing from the fundus, weighed seven

Digitized by Google

pounds. The cavity of the uterus was not enlarged. The abdominal wound was closed with twenty-five silk stitches, and the operation was done under the spray, with Listerian precautions. The serre-nœud came away on the fourteenth day. The temperature never exceeded 99°, and the patient left for home in six weeks, able to sit up, and, though still somewhat an invalid, much improved in general health. Though the tumour was not large by weight as such tumours go, yet it was relatively large both in appearance and effects in this very fragile and slim person.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Lymphadenoma.—Congenital Umbilical Hernia.—Carcinoma of Pancreas and Semilunar Ganglia.—Guttural Pouches of Horses.—Dilatation of Œsophagus.—Myxoma of Skull.—Aneurysmal Varix.—Rectal Polypus.

THE first meeting of the winter session of this Society was held on Tuesday last, Dr. J. Syer Bristowe, F.R.S., Vice-President, in the chair.

Dr. HADDEN showed specimens of Lymphadenoma, in which the intestinal glands were extensively affected. The patient was a man aged fifty-four, who had suffered for several months from abdominal tumour. He had effusion into the serous cavities and enlargement of the spleen. The abdomen was tapped twice, and the fluid withdrawn was milky, as in chylous ascites. Before death pus formed in the anterior chamber of the eye. The temperature was usually normal, and nothing special was noted about the stools at the necropsy. The abdominal tumour was found to arise in enlargement of the mesenteric and retro-peritoneal glands. All the lymphatic glands of the body were enlarged, and secondary growths were seen in several organs, especially in the spleen, which was much enlarged. The glands of the small and large intestine, agminated as well as solitary, were enormously enlarged; but the coats of the intestine were not infiltrated, as in the recorded cases of Dr. Murchison and Dr. Coupland. The author directed attention to the milky nature of the effusion in the serous cavities, and suggested that it might be due to the same cause as a chylous ascites.—Dr. BRISTOWE remarked that the enlargement of the lymphoid tissues was remarkable in being limited to the glands and not invading the parietes, as in Dr. Coupland's and others' specimens.

Mr. D'ARCY POWER showed specimen and drawings of Congenital Umbilical Hernia. He was indebted to Mr. J. J. de Zouche Marshall of Lamberhurst for the history. The mother of the child, born at full term, is a healthy young woman. The hernia was discovered as a transparent sac containing several coils of small intestine, situated in the umbilical cord at the part nearest to the child's abdomen. The cord was ligatured and divided in the usual manner, and an ineffectual attempt was then made to get back the bowel through the umbilical opening. After gentle taxis for ten minutes without success, the sac was carefully opened on a director, and as the gut could not yet be returned the umbilical ring was enlarged. About a foot of the intestine was then with some difficulty returned into the abdomen. The edges of the ring and of the wound were next brought together with silver wire and carbolic dressing, the whole being supported with lead plaster and a bandage. The child died at the end of three days of peritonitis. Antonio Scarpa and Sir William Lawrence in their treatises on ruptures had given a complete description of this hernia. Usually this malformation was accompanied by spina bifida. The tumour appeared to be formed by a dilatation of the coverings of that portion of the umbilical cord which was nearest to the body of the child. It had a fusiform shape, with the main constituents of the funis running as a bundle along its lower border, the umbilical cord again appearing at the distal apex of the swelling. The external surface was polished, and closely resembled the outer surface of a cord; whilst internally the sac was covered with a smooth layer, which was apparently derived from the peritoneum. It contained about a foot of small intestine, and at a short distance beyond the tumour was a second small sac filled with a viscid fluid.—Mr. E. J. GODLEE had seen two cases of hernia into the base of the umbilical cord; the outer surface of the tumour becomes dried into caky brown masses. In one case strangulation necessitated operation, but the patient died shortly, as the other did, without operation.—Mr. F. TREVES had had five cases under his own care. Twenty cases had been recorded, and the majority were covered by thick tissues and surrounded by a substantial sac. In a few instances the sac wall was very thin. Imperfect closure of the visceral plates was the chief cause of the hernia. If not the cæcum, then a Meckel's diverticulum was the most likely constituent of the hernia. The bulk of cases require immediate operation, for the skin over it becomes dry and inflamed. It would be wiser to lay open the sac, reduce the contents, and bring the edges together. In nearly all the reported cases of this variety there was no other deformity.

Dr. HALE WHITE showed Microscopic Sections of the Semilunar Ganglia which had been invaded by scirrhus spreading in from the pancreas. The patient was a woman aged fifty-four, whose only important symptoms during life were a vague abdominal pain, wasting, and vomiting. The growth was situated in the centre of the pancreas, both head and tail being free. A portion of the jejunum was bound down to the pancreas, and thus partially constricted. The nerve cells in the ganglia were granular and slightly pigmented. The cancer had spread along the bundles of nerve fibres in the semilunar ganglia, so that sometimes a bundle of nerve fibres would be replaced by a tube of cancer cells, bound in by the dense fibrous tissue surrounding the nerve fibres. The vomiting might well be explained by the constriction of the intestine and the wasting and the vomiting, so that we had two organs, the pancreas and the semilunar ganglia, both affected by growth, and yet no symptoms were produced that could with certainty be attributed to their implication. Dr. Hale White thought this case supported his view advanced in the *Journal of Physiology*, that the semilunar ganglia were organs which in us were dying out both physiologically and structurally. It was to be noticed that here the nerve cells were not more granular than they frequently are in individuals in whom no disease of the ganglia is known to exist.

Mr. BLAND SUTTON showed specimens of Guttural Pouches of Horses. In these animals the Eustachian tubes formed large sacs, and might be so large as to hold six or seven ounces of plaster, and they take up the space in the horse which corresponds to the pharynx of man. They communicate by means of a narrow valvular orifice with the posterior nasal passages. Some suppose that they substitute the function of the mastoid cells, which are ill developed. The sacs are very liable to inflammation, and the narrow orifice causes the secretions to be retained; suppuration may occur, and necessitate operation of letting out the pus through the skin, which they distend between the styloid process and the lower jaw.—Dr. COUPLAND asked whether these concretions had been microscopically examined, for they might be formed on a basis of grass or other foreign body.—Mr. F. TREVES asked whether the fossa of Rosenmüller had any relation to the guttural pouches of horses.—Mr. SUTTON, in reply, believed that Dr. Coupland's suggestion might be a true explanation, and he agreed with Mr. Treves that the pouches might arise as dilatations of the Rosenmüller fossa.

Dr. HANDFORD showed a specimen of Dilatation of the Œsophagus taken from the body of a man aged fifty-two, who had suffered for more than five years from regurgitation of food. This occurred many times daily; sometimes immediately after meals, occasionally half an hour or an hour after. He was at the same time suffering from advanced heart and vascular disease, of which he died six days after admission into the Nottingham General Hospital. At the necropsy the heart was found much enlarged, the aortic valves incompetent, and the aorta enormously dilated. This dilatation affected the whole of the thoracic aorta, but was much diminished at the lower part. The œsophagus was very markedly dilated throughout its whole length, except at its passage through the diaphragm, where it was constricted to very slightly less than the normal size, but there was no induration or sign of stricture; it contained several ounces of undigested food. After being opened and preserved for several months in spirit, its greatest width was three inches and a half. Just above the cardiac orifice it was one inch and three-quarters. Microscopic sections were examined, but no very marked changes were found. There was no disease of the stomach. Dr. Handford thought it possible that the dilated aorta in its passage through the diaphragm

Digitized by Google

might have pressed the œsophagus against the central tendon, and so interfered with the free passage of food. Other possible causes were general muscular atrophy, as in the cases recorded by Klebs and Luschka, or disease of the vagus. Dr. Handford did not consider it a case of simple congenital stenosis.—Dr. BRISTOWE referred to a case which showed symptoms only three months before death, and probably due to mere catarrhal or inflammatory changes; at least, there was no stricture. Was the condition recognised during life? The answer to this was in the negative.

Dr. JACOB of Leeds showed a specimen of Myxoma of the Skull. During life the man exhibited an enlargement of the skull. There was but little inflammatory condition. Under the microscope there was only myxomatous structure, and not of the syphilitic type. There was a large overgrowth of the calvaria in the parietal region, and apparently chiefly of the diploë. The specimen was referred to the Morbid Growths Committee.

Dr. A. ROBINSON showed an Aneurysmal Varix taken from the amputated stump of a man aged thirty-two, who had had his leg amputated sixteen years previously through the upper third. There had been much pain in the stump since a blow which it had received two weeks before he was seen, when expansile pulsation was discovered. The aneurysm, the size of a small orange, was excised, and the varicose veins were removed from the soft posterior part of the stump.

Mr. MARMADUKE SHEILD exhibited a Villous Polypus of the Rectum, removed from a woman who had suffered for eight years from syphilitic disease of this part. The growth used to prolapse from the anus. It was a lobulated and foliaceous pediculated growth, recalling the appearance of a pancreas. The tumours were somewhat rare. They did not infiltrate the rectal wall, and rarely if ever recurred.

The following card specimens were exhibited:—Mr. F. S. Eve: Part of an ancient Egyptian Skull affected with Osteoporosis. Mr. P. D. Turner, for Mr. Christopher Heath: Villous Tumour of Bladder and Surgical Kidneys. Dr. H. A. Lediard (Carlisle): (1) Melanotic Sarcoma growing from the Edge of the Nail of Index Finger; (2) Sarcoma of Palate in an Otter Hound; (3) Large Subcutaneous Nævus from the Parotid Region.

CLINICAL SOCIETY OF LONDON.

Pemphigus; Arsenical Pigmentation; Unusual affection of Cicatrix.—Recovery from Bullet Wound of Liver.—Pulmonary Arterial Reflux.—Cephalhæmatoma over Right Parietal Bone.

THE first meeting of the winter session of this Society was held on the 14th inst., Dr. W. H. Broadbent, F.R.C.P., President, in the chair.

DR. HANDFORD reported a case of Pemphigus occurring in a child, aged thirteen, and terminating in incomplete recovery after nearly a year. The limbs, trunk (except parts of chest and abdomen), face tongue, mouth, pharynx, mucous membrane of nose, conjunctivæ, and orifice of the vagina were all affected. The eruption came out in crops, and was accompanied by rise of temperature. Micro-organisms were found in the bullæ which contained pus, but not in those which contained serum. Quinine in large doses was given with benefit, and arsenic. Of the latter fifteen-minim doses of Fowler's solution were given thrice daily, and continued for ten weeks. After this, the skin of the whole body was noticed to be dry, brawny, and darkened in colour. The axillæ, groins, and abdomen were almost as dark as in Addison's disease. The skin looked dirty, but the colour was proved to be due to pigment—deposited chiefly in the rete, but partly in the more superficial epithelium. The arsenic was stopped, and the patient treated by wet-packing, and in a month the skin had resumed its normal, smooth, moist appearance, and much of the pigmentation had disappeared. Also on the hands and feet there were many elongated patches of cicatricial-looking skin, thickened and elevated. These patches were covered with white points, like millet seeds, just beneath the epithelium, and resembling to the naked eye miliary tubercles. They were not tubercular, but consisted of accumulations of degenerating epithelial cells in the deeper part of the epidermis. They disappeared in four or five months. It is possible that this condition also was due to the arsenic. Several coloured drawings and photographs illustrating these conditions were exhibited. A third case of pemphigus was described, in which there was some ground for suspecting implication of the mucous membrane of the intestinal canal. It presented also the atrophied glossy condition of the skin of the hands mentioned in the first case, and which is so suggestive of an implication of the peripheral nerves. No definite affection of sensation or of the reflexes, however, could be discovered, though reference was made to the statement of Dr. Pasquale Ferraro that he had found advanced changes of an atrophic degenerative nature in the posterior horns of the dorsal spinal cord, and also in the peripheral nerves, the ganglia on the posterior nerve roots, and in the sympathetic ganglia. Two further instances of arsenical pigmentation were narrated, and the opinion was expressed that small doses of arsenic (five to ten minims of the liq. arsenicalis) repeated thrice daily for about two months were capable of producing a pigmentation of the skin, chiefly of the abdomen, lower part of the chest, lumbar region of the back, axillæ, groins, and inner part of the thighs. This condition was not necessarily accompanied by roughness and dryness of the skin and disappeared slowly in from one to four months, or rather longer.—Dr. RADCLIFFE CROCKER had seen white spots or specks in one case of pemphigus in the Great Ormond-street Hospital for Sick children; their probable nature was the same as that of milium. He had frequently seen pigmentation follow the use of arsenic even in cases of chorea as well as of recurrent bullous erythema. The pigmentation appeared to be due to an actual deposition of the metallic arsenic chiefly in the deeper layers of the epithelium; the duration of this pigmentation varied from not less than four to even as long as twelve months and perhaps longer. He could not agree that the photographs handed round were representations of pemphigus foliaceus, which is absolutely universal and consists in a continuous eruption of flaccid bullæ.—Dr. GOODHART was interested in the occurrence of high fever in pemphigus, which appeared to be independent of the eruption, and perhaps depended on individual peculiarity or some general condition of body. Pemphigus was undoubtedly controlled by arsenic, but large doses might be required to effect this control, even as much as eighteen to twenty-two minims three times a day. He had also witnessed marked pigmentation frequently as the result of the administration of arsenic.—Sir DYCE DUCKWORTH testified to the value of arsenic in pemphigus, and had seen cases completely cured by its employment though large doses might be required and pigmentation result.

Dr. LEDIARD read a paper on a case of Bullet Wound of the Liver. The case was one in which a constable was shot through the body, at a short distance, whilst pursuing some burglars. The bullet entered the right side of the chest, between the seventh and eighth ribs, a little to the outer side of the mammary line. Deep collapse resulted, during which the bullet was extracted from the right loin, just over the last rib, and two inches from the spine. It is believed that the constable was leaning forward to catch a man in front of him when he received his wound. Jaundice supervened, and on the ninth day the extraction wound in the back discharged a large amount of bile-stained fluid, and continued to do so to a less extent for some weeks. Evidence of air in the right pleural cavity to a limited area was also present, and subsequently an empyema formed and discharged freely a large amount of pus through the bronchi. Elevation of temperature lasted more or less for fifty-eight days, but at the end of three months the patient was convalescent, and has made a complete recovery, being still in the Cumberland police. The course of the bullet was probably through the convex surface of the liver, the diaphragm being perforated twice, and the lung grazed. The presence of bile was ascertained by chemical tests, corroborated by Dr. Walker, of Newcastle, public analyst for Carlisle. The microscope also gave clear evidence of a wound of the liver tissue. The bullet was a large one, and weighed three drachms and a half.

Sir DYCE DUCKWORTH read a paper on a case of Pulmonary Arterial Reflux. The patient was a man aged forty-nine, invalided from the police on account of short-windedness and cough. He came first under care at St. Bartholomew's Hospital in March, 1884, with a history of winter cough for five or six years. He had suffered from several attacks of gout in the feet. He had taken rather freely of beer and rum. His father was a gouty man, and died paralysed at the age of sixty. There was no history of syphilis. His complexion was then dusky, and the chest barrel-shaped.

Digitized by Google

There was an increased area of cardiac dulness. At the apex, which was felt in the sixth space in the left nipple line, was a fairly natural first sound and a faint distant murmur. A clear second sound was also heard here. Above the apex and over the whole præcordia a diastolic murmur was heard, loudest over the aortic area. The pulse was jerky and not quite regular. The legs were œdematous. There was no albuminuria. Signs of general bronchitis in the lungs. On one occasion he spat two ounces of dark blood mixed with mucus. The case was regarded as one of "morbus cordis," aortic regurgitation, chronic bronchitis, and emphysema. In November 1885 the patient returned to the hospital under the care of Dr. Gee, suffering from aggravated bronchitis and orthopnœa. The heart's apex was impalpable, and cardia dulness was absent. A diastolic murmur was heard all over the præcordia, loudest over lower end of sternum. The pulse was irregular, 50 per minute, of fair volume and not jerky. The urine contained a trace of albumen. His board was headed, "Aortic regurgitation, with cough and gout." After two weeks he went out relieved. His third admission was to the John ward, in January, 1887, under Sir Dyce Duckworth. The patient was then very dusky, bloated, and dropsical. The jugular veins were turgid. There was much bronchitis, and very little urine was passed. The latter contained one-sixth of albumen. There was orthopnœa and much flatulent distension of the abdomen. Cardiac impulse was felt in the fifth space, half an inch inside the left nipple line. Very limited dulness was made out on percussion. There was epigastric pulsation. At the apex a systolic murmur was heard, also in the axilla or lower angle of left scapula. A diastolic murmur was audible at the apex and base, loudest down the sternum. It was particularly noticed that the sound was defective in the area of the pulmonary artery. The pulse was 78 per minute, irregular in form and volume, and of increased tension. No collapsing or "aortic" quality was noted. Much bronchitis and emphysema. The liver was enlarged. Throughout there was a subnormal temperature. The sputum was copious, not aerated, viscid, and dirty greenish-yellow in colour. An attack of gout occurred in the left great toe and instep. Treatment proved of little relief. Increasing cardiac dilatation and œdema of the lungs supervened. Sphygmographic tracings of the pulse were taken with several instruments, and gave no indication of aortic reflux. The patient lingered, slowly failing, till March 6th. At the necropsy the lungs were found emphysematous and œdematous. Pericardium natural. Heart very large, with much dilatation, especially of right ventricle. The mitral and tricuspid orifices were dilated. The aortic valves were natural. The pulmonary valves were two in number, one large one with much thickened edges, and one smaller one with similarly thickened edges. Between the two was a vacant space showing some roughening at the site where a third valve should have existed. Below this was an aneurysmal pouch which would have held a large hazel nut. The ventricular septum was complete. The viscera showed the usual signs of long-continued obstructive cardiac disease. The heart and a drawing of the parts in a recent state were exhibited. It was probable that this was a case of congenital disease of the pulmonary valves, the heart valves only failing in middle life. Sir Dyce Duckworth remarked that it was perhaps hardly creditable that a correct diagnosis was not made in this case. He had, however, once made a diagnosis of pulmonary regurgitation, which at the necropsy turned out to be aortic reflux, and was thereby made cautious. The physical signs of aortic regurgitation were sometimes more plain in the area of the pulmonary artery, and the most careful auscultators would probably always be cautious in making a diagnosis in these very rare cases. The sphygmograph would perhaps be of the best avail in supporting a suspicion of the disease in any doubtful case.—Dr. BROADBENT considered that a better diagnosis during life could not have been made, and he should certainly have suggested the presence of aneurysm. He asked for further particulars as to the anatomy of the aneurysm of the pulmonary artery.—In reply to Dr. Coupland, Sir DYCE DUCKWORTH said that he could not remember whether the cardiac second sound was heard in the carotid artery or not.—Dr. DOUGLAS POWELL agreed that diagnosis could not be made with certainty, and he said there was difficulty in discovering regurgitation from the arteries in some cases of mitral stenosis.

Mr. TARVIN gave an account of a case of Cephalhæmatoma over the Right Parietal Bone in a boy aged eleven. The cyst formed an enormous tumour that projected some two inches from the surface of the skull; it was surrounded by a wall of thick bone. The cyst was the result of a fall upon the head when the child was six months of age. Mr. Treves described the formation of these cysts in the newly born. The present case is rare, as showing a cephalhæmatoma, the result of injury, that had formed a permanent tumour. It was of interest also in showing that the bone, that is so common about these cysts, had not undergone absorption. So far as reported examples and museum specimens go, the present case would appear to be unique. No treatment was proposed.

MEDICAL SOCIETY OF LONDON.

Psychology of Joking.—Simple Dilatation of the Stomach.

THE first ordinary meeting of the 114th session of this Society took place on Monday, Oct. 17th, 1887.

An introductory address was delivered by the President Dr. HUGHLINGS JACKSON, on the Psychology of Joking; a report of which will be found in another part of our present issue.

Dr. CLIFFORD ALLBUTT read a communication on Simple Dilatation of the Stomach. He pointed out that simple gastro-ectasis, both acute and chronic, and independent of pyloric obstruction, was often overlooked; that indeed many physicians have been disposed to ignore it in an uncomplicated form. Since the publication of his first paper on the subject in 1879 (which was based on an increasing experience from the date of Kussmaul's well-known essay in 1869) he had added greatly to his cases and notes, but he feared with few new results. He found, however, that the malady was not uncommon in advanced stages, and common enough in lesser degrees, both in acute and chronic forms. He urged the great importance of diagnosing the disease, whether as a complication of febrile or debilitating illness, or as a result of prolonged gastric derangement, and as a malady to which infants, youths, and adults were all liable. Without diagnosis proper treatment could not be employed, and such diseases as phthisis thus complicated must go from bad to worse, if not specially treated. In infancy and early childhood this malady might seriously impair nutrition. The more important symptoms of gastro-ectasis in children and adults were briefly discussed, and also the relations of gastro-ectasis to gastric catarrh. The influence of chronic diseases and of gross or injurious habits of feeding in inducing dilatation were next indicated, the results of some of these habits being to produce only the lesser degrees of dilatation; also the influence of general or local nerve failure in allowing ectasis to occur was considered. That gastro-ectasis was commonly associated with great nervous irritability and depression, whether as cause or effect, was undoubted, as was the association of vast and transient distensions with hysteria in women, though in this sex permanent gastro-ectasis was less common than in men. Although fully developed dilatation was not difficult to diagnose, and even to measure, yet lesser degrees required more care and were more difficult. Succussion might not infrequently be obtained in stomachs presumably of normal dimensions, and in some cases the whole stomach might be displaced downwards; therefore, in acute cases especially, the upper stomach boundary should be carefully noted. For treatment washing out was urged as the essential basis of all success, whether for relief or cure. The action of the stomach syphon upon the dilated stomach was to be compared to that of the catheter upon the enfeebled bladder, the mischief in both instances being perpetuated by the retention of decomposed matters in the cavity.—Dr. STEPHEN MACKENZIE advocated the use of Leiter's funnel and tube for washing out the stomach.—Dr. HABERSHON suggested that those cases of dilatation associated with phthisis were probably due to lesion of the pneumogastric nerve. In addition to washing out the stomach, he was in the habit of prescribing carbolic acid and hyposulphite of soda to prevent fermentation.—Dr. C. J. HARE considered an emetic a most valuable remedy in cases of moderate dilatation.—Dr. THEODORE WILLIAMS suggested that these cases should be treated by rectal alimentation in order to ensure rest to the overworked stomach.—Dr. LAUDER BRUNTON thought that in some cases the dilatation was of careful reflex nervous origin. He insisted on the importance of dietetic and medicinal, in addition to mechanical, treatment.

Reviews and Notices of Books.

Elements of Pharmacology. By Dr. OSWALD SCHMIEDEBERG. Translated by THOMAS DIXSON, M.B. Pp. 223. Edinburgh: Young J. Pentland. 1887.

SCHMIEDEBERG'S views have recently been so largely quoted that we are glad to welcome an English edition of his "Elements of Pharmacology." It is a book of a peculiar type. It is intended to serve as a pharmacological commentary on the second edition of the German Pharmacopœia, and thus occasionally deals with substances not recognised as official in the British Pharmacopœia. The author's plan has been, not to give directions for the treatment of disease, but to describe the actions of powerful agents, to characterise the consequences which may affect the entire organism, and "from pharmacological facts to formulate general rules for the employment of remedies." The precise meaning the author assigns to the term *pharmacology* is the study of the changes in general which are caused in the living organism by chemically active substances, whether these substances are used for remedial purposes or not. This definition is broad enough to include numerous active substances for which at present no therapeutic values are claimed. Indeed, it is suggested, probably correctly, that when a remedy has fallen out of therapeutic use, subsequent experimental researches may prove of value in indicating the advisability of its employment in some totally new directions. Waves of fashion may take up and toss aside new remedies without realising their value, but the pharmacologist working laboriously and methodically may yet find unsuspected treasures in them. Cocaine, in its application as a local anæsthetic, is sufficient proof of the truth of this idea, its value and employment as a tonic having been completely overshadowed as soon as its local effects were discovered.

The introduction is brightly written, although it deals with definitions, with the nature of pharmacological actions, the sources of therapeutics, the choice of remedies upon rational principles, and the classification of pharmacological substances and of remedies. The semi-historical considerations of the sources of therapeutics are written in a light vein of sarcasm, indicating the author's contempt for all that has preceded what he regards as a rational system of therapeutics based upon pharmacological researches. On the other hand, his nationality might be guessed from the gravity with which he asserts that "distilled water, when taken as a drink, does not act as a poison simply because it is changed into a harmless form immediately after its absorption, through mixing with the substances dissolved in the blood and fluids of the tissues." To this idea he reverts later on when (p. 115) he tells us, "Water as such never comes into contact with the living tissue, but becomes transformed into a solution while it is still in the stomach; at all events, it only enters the blood in this form." The introduction is followed by a long chapter on nerve and muscle poisons. This is divided into sections of very unequal length and value; of the strychnine group it may be sufficient to say that we are furnished with a concise *résumé* which does not add materially to our knowledge. The curara group similarly is disappointing in being silent, or almost so, concerning other substances having like properties. In small type we are informed that "many *ammonium bases* cause, along with other actions, a paralysis of the ends of the motor nerves, just as curara does. Whether one or other can replace curara further investigations alone can show." In fact, here we find the keynote of the book. The author appears to wish us to meet in his work with what is *true* rather than with what is *new*, and we may search in vain for recent statements if, in his opinion or in that of the number of younger investigators working under his guidance, the statements are not conclusively established as facts.

Morphine is dealt with at greater length and with a more satisfying result, the explanation of the supposed stimulation of the brain being very pithily expressed as "merely a matter of the disturbance and of the alteration of the equilibrium of the separate functions of the brain. The area for ideation is evidently quite intact when sensory stimuli are already beginning to lose their effect." Concerning the influence of alcohol upon the brain, the author holds that from the beginning no true stimulation can be traced. He regards the phenomena observed as merely "the results of the commencing paralysis of certain portions of the brain. In the *mental areas* the finer degrees of *observation*, *judgment*, and *reflection* are the first to disappear, while the remaining mental functions remain in a normal condition." The section upon nerve and muscle poisons necessarily includes a consideration of a very large number of important remedies. It is followed by a chapter dealing with substances which, through their molecular properties, cause alterations of various kinds at the point of application. Of aromatic and bitter stomachics he remarks that "many are quite antiquated and others quite superfluous," and he is accordingly satisfied with a somewhat bald enumeration. Succeeding chapters deal with the action of water and of saline solutions; chemical cauterisation by means of acids, halogens, and oxidising substances; the compounds of the heavy metals and aluminium as nerve poisons, muscle poisons, and escharotics; and finally, brief space is assigned to the aromatic compounds, digestive ferments and food stuffs, and to remedies acting mechanically and physically, including a consideration of the uses of plasters, ointments, poultices, and fomentations. Throughout the author exhibits a mild scepticism as to the value of purely therapeutic researches; this may perhaps be best illustrated by the following remarks upon nitrate of silver: "This neurotic drug in course of time has had to pass through *great vicissitudes*. While it was recommended most warmly by some physicians, others rejected it just as decidedly. For a time it fell even totally into oblivion, but only to appear once more. At present its use as a neurotic is again on the wane, but will probably increase again, as has always been the case."

Dr. Dixson has performed his part very satisfactorily, the English rendering being clear and idiomatic, and very rarely indeed betraying the fact of translation. Our thanks are due to him for bringing such a valuable work within the scope of a wider circle of students.

The Topographical Anatomy of the Child. By JOHNSON SYMINGTON, M.D., F.R.S.E., F.R.C.S.E., Lecturer on Anatomy, School of Medicine, Edinburgh. Edinburgh: E. and S. Livingstone. 1887.

DR. JOHNSON SYMINGTON has well filled a gap in our Topographical Anatomy. This department of anatomical science has been worked at most extensively and ably by Pirogoff, Braune, Luschka, and others in the adult; but the method of frozen sections has hitherto been systematically applied to the child, in one case only by Prof. Dwight. Dr. Symington has added to our knowledge by presenting us in this work with fourteen coloured lithographic illustrations, all life size, and thirty-three woodcuts taken from sections of male and female children, aged four years and a half, five years, six years, and thirteen years, and has given us a large number of very accurate observations on the position of the various organs and viscera, and the changes which they undergo in the earlier periods of life. The horizontal sections have been taken from a girl six years of age, whilst the vertical sections (both coronal and sagittal) are from children of both sexes and various ages. In

Digitized by Google

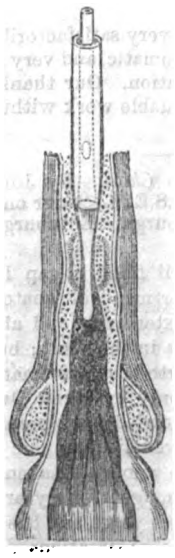
addition to the illustrations, the work is most valuable for excellent letterpress treating very fully and minutely of the position of structures at all periods of early life, and it is evident that many of the views generally held in regard thereto will have to undergo considerable alteration. For example, Dr. Symington shows that the external auditory meatus is relatively as long in the child as in the adult, when examined in the fresh state in subjects with the entire head frozen; that the spinal cord in the newly born child ceases at much the same point as in the adult; that the child's neck is not relatively short, but that it is higher in relation to the vertebral column than in the adult. The common assumption that the position of the stomach in the child is vertical is also shown to be erroneous, and is proved by figures taken from an infant four days old, and from the girl six years of age. The portion of the book devoted to the position of the pelvic viscera in male children is of great importance to surgeons, and will be carefully studied in view of operations on the urinary organs in early life. Too much praise cannot be bestowed upon the author for the obvious care and industry with which he has pursued his investigation, and the accuracy and fidelity with which he has reproduced its results. Its dedication to Professor Braune is a most graceful compliment to an anatomist who has done more to advance the knowledge of topographical anatomy than any other worker in this special branch. In conclusion, we must add a word of praise for the artist, Mr. J. T. Murray, and for Messrs. McLagan and Cumming, who have printed the plates.

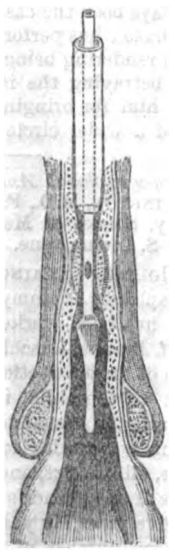
New Inventions.

NEW URETHRAL INSTRUMENTS.

THE first instrument, as represented in Figs. 1 and 2, is what I term the Compound Catheter. Outwardly, as Fig. 1 shows, this instrument is practically the same as the French gum-elastic bougie, but upon referring to Fig. 2 it will be seen that where the stricture is too tight, and will not,

FIG. 1.





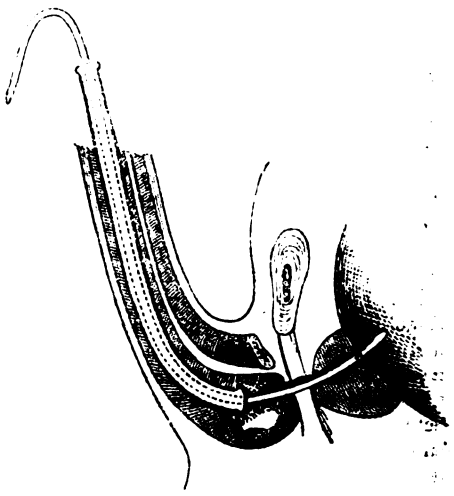


FIG. 2.

or should not, allow the whole instrument to pass, the body or dilated portion can be withdrawn, and the inner or smaller catheter passed on without fear of causing pain to the patient or injury to the mucous membrane. The next instrument, Fig. 3, I call the Catheter Guide or Conductor, and it acts in a double capacity—firstly, for protecting the mucous membrane of the urethra from unnecessary thrusts and stabs, and secondly as a stricture threader. The conductor resembles an ordinary silver bougie—flat, however, at both extremities, with slightly protruding edges; and it contains a central tube capable of admitting a No. 1 and No. 2 catheter, and this is surrounded by a number of smaller tubes for the passage of catgut or fine bougies. Let a stricture be situated where it may, a full-sized catheter can always be passed down to it; the conductor then takes the place of the catheter; this is passed as far as it will go, and its face is pressed gently against the anterior opening of the stricture, in order to dilate it; a long fine catheter, purposely made for the conductor, is then passed down the central tube, and rarely fails to pass through the stricture

FIG. 3.

on reaching it; should it fail to do so, the smaller tubes with catgut can then be worked. Even after failure with all the tubes, we may have the satisfaction of knowing the urethra has been protected from rude treatment, the mucous membrane being saved many a bruise, many a laceration. Failure, however, will not often attend the conductor, if used in a rational manner. A glance at Fig. 3 will possibly serve to illustrate its use. These instruments have been made for me by Messrs. Walters and Co., of 29, Moorgate-street, City. I venture to think that those who may be disposed to try my instruments will not be disappointed with the result. The conductor, especially in intractable cases, will be attended with marked benefit both to patient and operator. E. DISTIN-MADDICK, F.R.C.S. ED.

"A CASE OF URETHRAL CALCULUS OF UNUSUAL SIZE."

To the Editors of THE LANCET.

SIRS,—I have just received the report of the examination of this stone kindly made for me by Mr. Richard Reynolds, of Leeds. As many inquiries have been made as to the composition of the calculus, I hasten to place Mr. Reynolds' report in your hands for publication.—Yours faithfully,

Queen-street, Leeds, Oct. 17th, 1887. W. H. BROWN.

[COPY.]

Report of the Result of a Chemical Examination of a Fragment of Calculus.

"The specimen was of dirty white colour, compact, and of flinty hardness, with a conchoidal fracture. It was composed of ammonio-phosphate of magnesia, and basic phosphate of lime, and these constituents were separated, and their respective presence was determined. From the physical character it may safely be asserted that the phosphate of lime predominated, and the result of the chemical test was consistent with this view. The urine from which the calculus was deposited would doubtless have an ammoniacal character. "RICHARD REYNOLDS."

THE LANCET.

LONDON: SATURDAY, OCTOBER 22, 1887.

THE reports of the proceedings at the opening of the medical schools in the provinces show that medical education is alive there as elsewhere. At two of the provincial schools we read of new buildings in course of erection; at Sheffield Dr. SINCLAIR WHITE intimated that the munificence of his senior colleagues and the public would before another year provide a new medical school; and at Newcastle-on-Tyne Dr. HEATH, long and honourably associated with the medical school there, said that they were engaged in the erection of a new college, which they expected to be worthy of the city of Newcastle, and as handsome as the Wood Memorial Hall. Apart from such substantial indications of demand for medical education and provision for meeting it, the proceedings were not without interest. Dr. SINCLAIR WHITE'S address was devoted chiefly to the exposition of the importance of sanitation, and was in its way most effective. He maintained that the aims of sanitary science and those of Christianity were practically identical, and that for people sunk in ignorance and depravity "sanitation must precede every other gospel." There was a mine of wealth, he maintained, in fresh air, water, and soap, and the cultivation of temperance. Dr. WHITE did not pretend that the successful inculcation of such principles was an easy matter; he does not expect mere legislation to do everything. He thinks that the Education Department might do more than it does in teaching hygiene in common schools, and he very properly pointed out the ignorance of many highly-educated people on the subject. Instances of this must have come under everybody's notice, and occur daily in the experience of medical men. Common cleanliness is commoner now than it used to be among educated people, though there are still surprising survivals of the opposite kind, and singular instances of ignorance of the virtues of fresh air. But Dr. WHITE'S appeal was in the interest of the poor, in whose straitened homes health and even decency are often impracticable. Arduous indeed is the undertaking of raising the standard of home comfort and accommodation among the people; but all must admit, in view of their tendency to forsake the country for the great towns, that it is urgently necessary, even in the interests of society itself.

A very interesting feature of the opening of the provincial session was the presence of a distinguished London teacher at Owens College and the Yorkshire School of Medicine respectively. It is a happy illustration of the good feeling which obtains between medical schools and teachers. The provinces in this matter, as in many others, set a good example to the metropolis. We sometimes hear plaintive accounts of the prolonged gestation of introductory addresses, and the months of unhappiness and anxiety which they involve to the unfortunate teacher who stands next in succession for this duty. Some of our young surgeons would rather remove a kidney or a cerebral tumour than deliver a simple introductory address. Let the metropolitan schools take a hint from the provincial ones, and ask one of the provincial teachers to address the students. It would give great freshness and novelty to the occasion, and though it would be difficult for any of our provincial brethren to give an address which would exceed the interest of that of Sir JAMES PAGET at Manchester or of Dr. MATTHEWS DUNCAN at Leeds, we venture to say that both these gentlemen would be well prepared to hear from provincial orators sound lessons in medical philosophy or in medical practice.

Owens College may well feel honoured in being the place of such a noble address as that of Sir JAMES PAGET. No student could hear it without feeling his sense of "responsibility to God and man" increased. The modesty with which Sir JAMES contrived to make his mistakes and his defects of observation do duty as a warning to his young hearers would not blind them to the rich wisdom and the rare magnanimity which appeared in every sentence. He may have missed—just missed—the significance of typhoid ulcers and of embolisms, which Sir WILLIAM JENNER and VIRCHOW and KIRKES so happily seized, but the education of his audience will not have proceeded far before they find out how much Sir JAMES has observed which others have overlooked, and how great are his contributions to pathology and practice, and above all to that higher region of professional thought and wisdom in which he reigns so easily and with such universal approval. Not the least important part of Sir JAMES PAGET'S address was that in which he dwelt on the value of private practice as a sphere for observation of facts, histories, and cases extending over long periods of time, and in which successive members and generations of a family of practitioners may take part.

The address of Dr. MATTHEWS DUNCAN is characteristic enough. Its praise of the Leeds school, started half a century since, "by the wise enthusiasm of a few medical men," was well merited. To him evolution is "that charming and valuable theory," but it leaves unsolved the great problems of conscience and responsibility. Continuity is a doctrine of the highest consequence, but it does not exclude forces which are not known to obey continuity. Schools had to provide for average men, but that did not exclude the necessity for individual effort, or hinder the workings of individual genius. His magnification of virtue was worthy of MILTON or of one of the great preachers of his own country. No good was to be expected in a medical school without this. In such a school the teachers would make shabby pupils, and the pupils would grow into mean practitioners. Dr. DUNCAN dwelt on the time necessary for medical education, and suggested that it would soon require five years, which practically is the period taken by the majority of students.

A PARLIAMENTARY PAPER has been recently printed and published containing copies of correspondence, or extracts therefrom, relating to the repeal of Contagious Diseases, Ordinances, and Regulations in the Crown Colonies. It is in continuation of other papers published this and last year, and is a most interesting document. It may be well to explain that soon after the repeal of the Acts in this country despatches were sent to the governors of different Crown Colonies—Ceylon, Hong-Kong, Straits Settlements.

Digitized by Google

Labuan, St. Helena, Malta, Fiji, Barbadoes, Jamaica, and Trinidad. In these despatches the various governors were notified that the policy of maintaining similar laws in the Crown Colonies would no doubt be called in question in Parliament, and that, if their respective Governments should be of opinion that the interests of the colony imperatively required the continuance of these laws, the Colonial Secretary wished to be furnished with any special reasons they might have for that opinion. These latter are included in the document alluded to, and, as they give most interesting information from the naval, military, and colonial surgeons, as well as the governors themselves, as to the efficiency of these laws in preventing venereal diseases, we will give them in detail.

From Barbadoes, Dr. F. B. ARCHER, the visiting surgeon to the Contagious Diseases Hospital, reports that the Act has done much good in the past and kept down disease amongst a certain class of prostitutes, but the powers of it are too limited, and it does not touch a very large class of women, who keep open houses and spread disease recklessly. He adds warningly: "I am certain, if the Act is repealed here, there will be a considerable increase of disease." He thus confirms what has been stated by those entrusted with the working of the Acts in this country and Ireland—viz., that its operations must, to be perfectly successful, embrace a wide area. He is confirmed in this conclusion by the Major-General in command of the troops. In St. Helena it appears that the Act, which was passed there in 1865 was allowed to lapse in 1879, and at present there is no law upon the subject. From Malta there comes a general opinion in favour of this ordinance from his Royal Highness the Admiral and Commander-in-Chief in a communication to the colonial surgeon. The Governor, Sir J. L. SIMMONS, urges with great reason that the legislation in Malta is not in any way the outcome of such legislation in England, but that, on the contrary, the existing law, passed in 1861 (three years prior to the first English Act of 1864), merely re-established the practice of inspecting prostitutes, which had been established probably more than 300 years previously. The temporary suspension of the practice in 1859 led to such serious consequences that it was found necessary to pass the Ordinance of 1861, which has been in force ever since. After alluding to statistics, to be given presently, he expresses a strong opinion that, quite apart from the question of the health of the military and naval forces, and looking to the civil population of Malta, the existing law should not be interfered with. Although Malta lies in the route of a great sea traffic, has a garrison averaging 3 per cent. of the total population, in addition to the seamen of the fleet, venereal disease is not prevalent, and bad forms of syphilis are relatively uncommon. The community is so small, and inter-marriage so universal, that any increase in the disease would lead to a serious spread of the infection throughout the community. It would therefore, as Sir J. SIMMONS argues, "be neither politic nor just to force on the Maltese the abolition of a hygienic safeguard which has existed certainly for more than a century, a safeguard which the maintenance by England of a garrison and fleet at Malta renders imperatively necessary in the interests of the Maltese themselves." Surg.-Gen. SINCLAIR gives the following statistics as to the troops under his command. In the year 1884 the Royal Malta Fencible Artillery (strength 374) gave no admission for syphilis. The Duke of Cornwall's Light Infantry (strength 900) arrived from England in December, 1885, with twenty-eight cases of venereal disease, and on Nov. 15th, 1886, they had only one case of gonorrhœa in hospital. The Black Watch (strength 740) arrived from Egypt on May 5th, 1886, with thirty-three cases of venereal disease; on Nov. 15th, 1886, they had no case in hospital. H.R.H. the Naval Commander-in-Chief, writes: "I am very strongly of opinion that in a place like Malta, with a very large garrison and fleet, and with, in addition, a large number of merchant seamen of all nationalities, constantly visiting the port, it is most desirable that the Acts should remain in force." He encloses a report from Deputy Inspector-General SHAW, who concurs entirely in the opinion of Surgeon-General SINCLAIR, and adds: "During my service at Malta I have found that the cases of venereal disease contracted in the island were not only very few in number, but very slight in character. This I attribute entirely to the sanitary action of the police regulations, which, if vigilantly and strictly carried out, render it impossible for a diseased prostitute to ply her trade for any time undetected; and the abolition of those regulations would, I believe, be fraught with evil consequences to the civil community, as well as to the garrison and fleet." Dr. PISANI, the chief Government medical officer in Malta, refers to the fact that the Maltese laws make it compulsory for any person and medical practitioner to report infectious disease within twenty-four hours of its detection to the sanitary authorities for the purpose of isolating them in proper hospitals or at the residence of the patients. He gives obvious reasons why venereal diseases should not be included among these, and urges that the ordinary source of venereal disease—the prostitute—can be well subjected to the measure of medical inspection, which secures early treatment. There is a consensus of opinion among the medical practitioners of Malta in favour of this inspection, and the women subjected to it do not object to it, and have given no trouble. He concludes: "I am convinced that inspection of prostitutes is here imperatively required, and that it should even be made oftener than it is at present."

It must be remembered, too, that the ratio of venereal diseases among the troops and seamen coming from the home ports and disembarking at Malta will now be enormously increased, it being well known that these diseases are as rampant amongst them as they were previously to the passing of the Acts in this country. If men of these classes are landed in Malta, and the prostitutes there are permitted to ply their trade unchecked by medical inspection and treatment in hospital, syphilis in its worst forms will soon become epidemic! It is most important, therefore, that the Government of Malta should in the most determined manner resist any attempt to repeal the existing law. The Maltese know from experience both the benefits of this legislation and the fearful consequences of its suspension in 1859. They have the most valuable of all arguments, the inexorable logic of facts. To ignore past experience, to disregard the strongly expressed opinions of governors, military, naval, and colonial medical officers ast and present, and to inflict

Digitized by Google

such evils on the colony as must inevitably result, would be nothing short of criminal.

In Trinidad the Act appears to have been practically imperative, and no medical details are given. From Hong-Kong, which resembles Malta in many respects, being insular, a great maritime highway, densely populated with an alien community, and other circumstances which make comparison with England impossible, comes the same general consensus of opinion in favour of maintaining intact the present legislation. This latter was commenced in 1857, seven years before the English Act of 1864. Previously to that year syphilis in a very severe form constantly prevailed, the type known as the "black lion" being very common. Dr. MANSON, one of the leading practitioners of Hong-Kong, informed the Administrator that the consequences of the suspension of the Act would be: "First, an epidemic of syphilis; second, this would continue until the point of saturation was reached; third, this state of saturation would be maintained until the existing or similar ordinances were reapplied." Inspector-General FISHER reports: "Venereal disease in China was formerly very prevalent among Her Majesty's forces in this command, and was of a much more virulent type and disastrous in its consequences than the same disease as existing in England. The local measures taken here have been of immense benefit, as shown by the smaller number of entries on the sick list and the milder nature of the attack. There is, however, every reason to suppose that the discontinuance of compulsory examination would soon be followed by results as serious as those of old." Dr. J. W. FISHER, Fleet Surgeon, states that in only one case out of all those contracted in Hong-Kong during the present commission has the disease been followed by constitutional effects, showing how wonderfully the more serious forms of syphilis have been stamped out by careful supervision. Speaking of Japan, Dr. FISHER adds: "The lock hospital system, combined with careful examination of all women belonging to the licensed brothels, has simply stamped out the old virulent form of syphilis which was for years associated with the name of Japan." He concludes: "I believe it to be the unanimous opinion of the naval medical officers serving on this station that the abolition or mere temporary suspension of the Acts would be attended with very grave consequences, and I have reason to believe that this is also the opinion of the medical officers of other navies." Similar testimony is borne by Major-General CAMERON commanding in China and Straits Settlements and by Deputy Surgeon-General HUNGERFORD. In addition to all this, it appears that the Acts have virtually suppressed a most horrible form of what amounted to brothel slavery, children being kidnapped and sold for immoral purposes. Mr. MARSH reports that "the women who are infected in this colony are carefully treated in the lock hospital, to which institution they manifest no repugnance after experience of the kind treatment they there receive." Very similarly favourable testimony in favour of the Acts comes from Jamaica, Fiji, Gibraltar, Straits Settlements, and Ceylon; no details are given respecting Labuan. It is much to be lamented that the discontinuance of the compulsory examinations is insisted upon in all except Malta and Fiji, where special circumstances render it imperative that they shall be continued. The Acts have been repealed in Jamaica, six members of the Council protesting against it in a very well reasoned paper. The Governor of Gibraltar (Sir A. E. HARDINGE) urges the continuance of the law, but apparently in vain. In Hong-Kong the brothels are to be still under police supervision and the lock hospital continued on the voluntary principle. We have been obliged to omit many other valuable details, but enough has been given to show the value of these Acts in the colonies as well as at home; and it is interesting to note the perfect agreement existing between the experiences and opinions of those who have had to administer them, both in these kingdoms and in the colonies.

THE question of the influence of scarlet fever hospitals on the neighbourhoods in which they are placed has been more than once brought under notice, and a communication which we have received from Mr. HENRY GODRICH, B.A., points out that the present time is one that is especially opportune for investigating the subject on the same lines that were adopted in the case of small-pox at the Fulham Hospital. We agree with him that such an opportunity ought not to be lost, but the relations of the Local Government Board to our metropolitan fever hospitals are of a sort that do not seem to favour inquiries like this, though urgently demanded in the interests of the community. It will be remembered how persistently the complaints as to the spread of small-pox were ignored, until at last Mr. POWER who apparently had no ordinary duties or responsibilities with regard to Fulham, was deputed to make an inquiry, the results of which finally upset all the views that the Metropolitan Asylums Board and the central authority had so long adhered to. In the case of scarlet fever, we are, it is true, in a somewhat different position, for the inquiries which were made some years back, when the official report on the Influence of Hospitals for Infectious Diseases was issued, went to show that, as regards the houses more immediately surrounding the London Fever Hospital, there had been no marked incidence of scarlet fever, and this although the number of patients suffering from that disease had often ranged from 500 to 900 per annum. But that inquiry did not profess to deal with the subject in the same exhaustive style as was adopted at Fulham, and the number of houses included in the investigation was so limited that protection against scarlet fever by a prior attack may to some extent have vitiated the conclusions drawn. And since that date Dr. TRIPE has brought forward some suspicious facts as to the influence of Homerton Hospital when used for scarlet fever isolation. Taking all these circumstances into consideration, it is only right that the question should be fully inquired into; and it will be obvious to everyone that the Medical Department of the Local Government Board can alone take the matter up in the manner which would be necessary to a successful result. Another point raised by Mr. GODRICH is the need for so constructing infectious hospitals that all infected air leaving the wards shall be effectually destroyed. He states that he originated the idea in a communication to the Kensington Vestry in 1877-78, and that it was only subsequently that it was advocated by Dr. BERTILLON and Dr. BURDON SANDERSON. We have often urged that such an experimental hospital should be erected for small-pox cases, and we still hope that

Digitized by Google

the managers of the Asylums Board will not long defer acting on the recommendation of the Royal Commission on small-pox and fever hospitals in this respect. But before there is any need to apply the system to scarlet fever, the public should have information from the proper source as to whether scarlet fever hospitals have, or have not, any power of distributing infection to the neighbourhoods around them by the process of aerial diffusion.

THE Harveian Orator, Dr. STONE, was fortunate in being able to import a really new theme into the annual panegyric of the man whose memory is so zealously and lovingly treasured by the College of which he was so brilliant an ornament. The publication in *facsimile* of HARVEY'S lecture notes on Anatomy, which was undertaken by the College mainly at the instigation of Sir E. SIEVEKING, was put to good account by Dr. STONE, who showed how full of interest these jottings are, and how much light they throw upon the character of HARVEY. The numerous quotations, in their quaint combination of Latin and English, which the orator culled from these manuscript pages, are full of wit and wisdom; and we doubt not that Dr. STONE will be repaid in the assurance that he has revealed to many the treasures of a priceless volume. For it is seldom that we are enabled to be brought into so intimate a contact with the living word as is possible by the perusal of these notes, which bring before the reader the man as he lived, as much as the anatomist and physiologist. But apart from the interest attaching to this exposition, Dr. STONE did not fail to urge upon the attention of the College the value and importance of a study in which he is almost alone in this country—viz., that of physiological physics. He did well to point out the defects in medical education in this respect, and he was by no means too severe in his criticism of the manner in which the University of London fulfils its duty of testing the "preliminary scientific" knowledge of students intended for medical graduation. His suggestion that a course of instruction in this subject should be one of the purposes to which the proposed new building on the Embankment may be put is one which may well be taken into consideration. Nor was the introduction of this topic at all foreign to the main object of a Harveian oration. The mechanism of the circulation may be taken as the root example of animal physics, and Dr. STONE showed by reference to HARVEY'S own words that he was not ignorant of the physical principles involved in the action of the heart, and that he paid much attention to the study of physical science as it existed in his day. With all his keen interest in scientific research, Dr. STONE nevertheless did not withhold an expression of regret at the neglect of classical training. He would fain have revived the ancient custom of delivering the oration in the Latin tongue, and hinted that the neglect of Latinity was depriving medicine of its place among the learned professions. We have no desire to revive an old controversy, but we may venture to differ from a conclusion which implies that culture is indissolubly linked with a more or less profound knowledge of dead languages. In HARVEY'S day Latin was the medium whereby students and teachers in all parts of the civilised world could exchange their ideas. To-day, the *savans* of the different nations speak in their own tongue, and education aims at imparting to each a knowledge of the languages used in other lands, so that the written thoughts can be disseminated in the freshness of their utterance, and not disguised or transmuted by being clothed in a dead language. We are less disposed, then, to agree with the opening sentences of Dr. STONE'S oration than we are with the just remarks he made on the close of his survey of HARVEY'S lectures upon the value of oral instruction. It has been often said that, owing to the multiplication of text-books, the practice of imparting knowledge by means of lectures has become unnecessary. In a few sentences Dr. STONE disposed of this shallow objection; and we commend his remarks to all those who would degrade medical education to the level of a schoolboy's task.

Annotations.

"Ne quid nimis."

THE ANNUAL MEETING OF THE COLLEGE OF SURGEONS.

THE annual meeting of the Fellows and Members of the College of Surgeons is now close upon us. The so-called report from the Council, which will be presented, will be found to consist of the Minutes of the Council meetings that have been held during the preceding collegiate year. With these Minutes, or rather, with the more important of them, our readers are already acquainted, for they have been published and commented upon by us from time to time. Nevertheless, it is desirable that Fellows and Members should make themselves thoroughly acquainted with them in order to appreciate the bearing of what may be said at the meeting. We accordingly recommend an early application to the Secretary for a copy of the report. Of chief interest at present is the attitude of the Council of the College to the Fellows and Members at large. The Council have applied for a supplementary Charter, containing, on the one hand, provisions at variance with the expressed wishes of a large section of the Fellows, and, on the other, entirely ignoring matters which the same Fellows believe would conduce to the welfare of the Royal College of Surgeons, and tend to promote the interests of medical polity and education. As regards the Members and their very natural aspirations to be admitted to some share in College management, the Council also reply with a direct negative. Thus the new Charter, which is now before the Privy Council, ignores the wishes of both Fellows and Members alike. Under these circumstances, it was felt necessary by the Association of Fellows and by the Association of Members respectively to petition against this supplementary Charter, and the matter is still *sub judice*. It appears to us, however, that the annual meeting will be a fit and proper occasion at which the Fellows and Members may again emphasise their disapproval of the course taken by the Council. To this end we hope there will be a large and influential meeting of both provincial and London men, and that the character of the proceedings will be such as to place additional arguments in the hands of the two Associations in favour of the views embodied in their two petitions now before the President of the Council.

THE SANITARY STATE OF CAMBRIDGE.

IT is singularly unfortunate that some of our university towns should lay themselves open to reproach on sanitary grounds, for as centres of learning they should not afford examples of that which can only result from failure to carry out the first principles of health requirements. This time Cambridge is in question, and Dr. Alfred Carpenter, who has

Digitized by Google

been there to co-operate with the University in granting certificates in Sanitary Science, can only express his disgust at the extent to which the sanitary needs of the town are ignored as regards sewerage and the filthy state of the Cam. Mr. R. C. Lehmann fully supports the complaints that are made, and it is evident from his statements as to the black, oozy, sewage stuff that is being dredged from the river, that intending Cambridge graduates will have to live on the banks of a filth-laden stream, and to boat in a solution of sewage. Mr. Lehmann throws the blame in the first instance on the Cambridge sanitary authority, who have ever since 1864 ignored their most elementary duty in this respect; and next on the Local Government Board, who after having held two local inquiries, and having then informed the Commissioners that, unless they formulated a complete scheme at an early date, a time would be fixed within which the work must be carried out, appear to have settled down into a condition of inaction. It is a matter of Imperial as well as of local importance, that such a place as Cambridge should free itself from such serious conditions of nuisance as are the result of the want of a proper system of sewerage and sewage disposal, and we can only wonder that those who are interested in the welfare of the town and university do not bring the subject before the attention of the House of Commons.

BERI-BERI AND ANCHYLOSTOMIASIS.

WE have received from Dr. W. R. Kynsey, Principal Civil Medical Officer and Inspector-General of Hospitals, Ceylon, a copy of a report on "Anæmia or Beri-beri of Ceylon." This singular affection, which has received of late years much attention in all parts of the world where it exists, has been attributed to a variety of causes. It is described as occurring under two forms—one which is marked by paralytic symptoms, the other in which a dropsical condition predominates. We published recently a full account of the affection, to which reference may be made for its peculiar characteristics, the most constant and striking of which is the progressive anæmia. There can, we think, be little doubt that the term "beri-beri" is an elastic one, and that more than one essential disease is included under it. Such, indeed, would appear from this fact alone, that its pathogeny has been by some ascribed to a bacterial source, by others to a poison which produces multiple neuritis, and again to the presence of intestinal parasites, such as the tricocephalus dispar (Erni), and the anchylostomum duodenale. Dr. Kynsey is persuaded that, in Ceylon at any rate, beri-beri (which is there of the "wet" or "dropsical" variety only) is none other than anchylostomiasis, more widely known, perhaps, under the various designations of "Egyptian chlorosis," "miner's anæmia," "brick-burner's anæmia," and the "St. Gothard Tunnel disease." The facts adduced by Dr. Kynsey in support of his contention seem to be strong, for he has detected the presence of this parasite in large numbers in all the cases he has examined. Certainly such an explanation is far more feasible than the alternative supplied by Erni in support of the tricocephalus. For, so far as we know, the latter parasite, which is exceedingly common in many countries, does not, like the anchylostomum, injure the intestinal wall and lead to hæmorrhage. The tricocephalus theory of beri-beri may rank with the bothriocephalus theory of pernicious anæmia, with even perhaps less justification. Nevertheless, the inquiry into the effect produced by intestinal worms upon the general health of their hosts is one which has been too much neglected, and the attention that is now being directed to the subject may result in the production of important additions to knowledge. The Ceylon form of beri-beri is free from the paralytic symptoms which are described as occurring from the first in other countries. It may run an acute or chronic course, and death is often appallingly sudden. The severity of the symptoms depends on the number of the parasites present in the intestines, the state of health, and the food. Residence in an infected centre is necessary for the development of the symptoms, the larvæ of the parasite being present in drinking water. If recognised early—viz., the dyspeptic or anæmic stages,—the disease readily yields to treatment; but if neglected until dropsy and cardiac degeneration set in, the prognosis is most unfavourable. Removal from the infected area is essential, and the best remedy for the expulsion of the anchylostoma is thymol, and for the anæmia iron, followed by digitalis or strophanthus. But no treatment avails until the parasites are expelled. The foregoing is the gist of Dr. Kynsey's conclusions. But he has added greatly to the value of his report by appending a translation by Dr. J. Macdonald of the admirable and exhaustive monograph upon "Anchylostomum duodenale and Anchylostomiasis," by Dr. Adolph Lutz, by far the most complete account of the parasite and its effects that has been published. A translation of Erni's article on Tricocephalus dispar and Beri-beri is also appended.

THE ROYAL BERKSHIRE HOSPITAL.

THE memorial, signed by twenty-eight medical men, forwarded to Mr. Benyon, president of the hospital, asking for the appointment of a Fellow, or at least a Member, of the Royal College of Physicians to fill the vacancy caused by the death of Dr. Shea, has been submitted to the Board of Governors, with whom rests the appointment of the candidate selected and approved by the medical and surgical staff. A fact of importance should be recorded in reference to the appointments to this hospital. For many years, we are informed, it has been the custom to appoint to the surgical staff those who are either the descendants of former surgeons, or those who have been pupils to one of the surgeons, or those who have been in partnership with them or their successors. This custom, whether accidental or intentional, has been rarely deviated from for a period of more than twenty-five years, except in the case of minor temporary appointments. The effect of such a custom is to shut out from the hospital able men from among the practitioners of the town and elsewhere, and naturally tends to discourage highly qualified men from becoming candidates when a vacancy occurs at the Royal Berkshire Hospital.

SMALL-POX ISOLATION AT PERTH.

A LIVELY discussion has been going on in Perth as to the propriety of the action adopted by the managers of the General Infirmary in retaining in that institution three nurses who had contracted small-pox in the performance of their duties. The disease having been imported, the patients attacked were removed to the small-pox hospital belonging to the sanitary authority; but the infirmary authorities declined to allow such removal in the case of the nurses, and this action has met with a protest from Dr. Simpson, the medical officer of health. Unless a general hospital has means for isolating small-pox in a completely detached building, with independent laundry, kitchen, and supervision, it is wrong to attempt the treatment of small-pox in such an institution; and the attempt has over and over again led to an extension of disease such as the ordinary patients have no right whatever to be exposed to. Even in the London Fever Hospital, where a separate and detached isolation building is available, the retention of a small-pox patient is never so much as contemplated. The real secret of the action which has been adopted in Perth seems to be that the authority's small-pox

Digitized by Google

hospital is not a proper one for the reception of persons holding the social standing which the nursing staff of the infirmary occupy. If so, the authority are to blame, and should forthwith remedy the evil; for it is their duty to protect the public from infection, whatever may be the social standing of those with whom the danger lies.

PROFESSOR BILLROTH.

THE numerous friends of Professor Billroth all over the world will be pleased to learn that his health is thoroughly restored, and that he has resumed his cliniques at the General Hospital, Vienna. On the occasion of his first lecture he received a great ovation. The theatre was crowded with professors and students for a long time before the lecture hour had arrived, and the entrance of Professor Billroth was welcomed with loud and long-continued applause. Dr. Preis then advanced and tendered in the name of his colleagues and the pupils a hearty welcome to the Professor, with an expression of joy at his recovery from so severe and dangerous an illness. In reply, Professor Billroth made some feeling remarks, recalling the time when, twenty years ago, he first taught in that place, with colleagues such as Rokitansky, Oppolzer, Skoda, Demme, Dittel, Hebra, and others, who had all since passed away. He warmly thanked those present for their kindness during his illness, and their reception of him that day. He had not expected to have been there again, but he had been snatched from death by the self-sacrifice and devotion of his colleagues. He spoke of the kindness and love which had been bestowed upon him on all sides, and said that he would devote all his strength to the welfare of mankind, the glory of the old Vienna University, and the prosperity of Austria. He then proceeded to speak of the life work of von Langenbeck, and suggested that, in respect to his memory, the meeting should be closed. After this, Professor Billroth took them over his wards, and operated on a case of double hare-lip.

OUR ARMY.

THE General Annual Return of the British Army for the year 1886, issued from the Horse Guards, shows the average strength to have been 7218 officers, 682 warrant officers, and 195,905 non-commissioned officers and men. Of these, 3556 officers, 441 warrant officers, and 94,060 non-commissioned officers and men were serving at home; and 3662 officers, 241 warrant officers, and 101,845 non-commissioned officers and men abroad. During the year the deaths among the non-commissioned officers and men, at home and abroad, amounted to 2721, or in the ratio of 13·89 per 1000 of strength, being slightly higher than in the preceding year. There were 2789 men discharged as invalids, or 14·24 per 1000, which is 4·51 per 1000 less than in 1885. The total loss from these two causes, therefore, was only 28·13 per 1000. There were 71,786 recruits enlisted, of whom 20,183 were rejected on primary inspection and 2410 on secondary, making a total of 314·7 rejected per 1000 enlisted. In the preceding year it only amounted to 290. Of 38,813 recruits who joined, 26 died and 49 were invalided within three months of the date of enlistment, and 335 were discharged at the end of that period "as not likely to become efficient soldiers," being respectively in the ratios of ·67, 1·26, and 8·63 per 1000, or a total decrease in three months of 1 per cent. Of the recruits who joined, 402 per 1000 were under nineteen years of age, 234 between nineteen and twenty, and 364 were twenty and upwards; this shows the unsatisfactory result of an increase of the younger class of recruits compared with the previous year. As regards the heights of the men passed into the service, the ratio per 1000 under 5 ft. 5 in. was 283; 5 ft. 5 in. to 5 ft. 6 in., 211; 5 ft. 6 in. to 5 ft. 7 in., 192; and 5 ft. 7 in. and upwards, 314. This shows an increase of 16 per 1000 in the proportion at 5 ft. 6 in. and upwards compared with the results for 1885. The chest measurements were—under 34 in., 350; from 34 in. to 35 in., 344; and 35 in. and upwards, 306, which are less favourable than in the preceding year by 5 per 1000 in the first group. The proportion at different weights was—under 120 lb., 187 per 1000; 120 lb. to 130 lb., 374; and 130 lb. and upwards, 439; the last being 20 per 1000 higher than in 1885. There would appear, therefore, to have been a falling off as regards age and chest measurements, but a gain in the heights and weights. It may not be uninteresting to compare these results with the ratios obtained regarding the non-commissioned officers and men serving on January 1st. Their heights were—under 5 ft. 5 in., 102 per 1000; 5 ft. 5 in. to 5 ft. 6 in., 176; 5 ft. 6 in. to 5 ft. 7 in., 206; and 5 ft. 7 in. and upwards, 517; the chest measurements—under 34 in., 72 per 1000; from 34 in. to 35 in., 159; and 35 in. and upwards, 769. No information is given as to the weights of the men serving. In addition to the effective force, the return gives a number of tables respecting the auxiliary and reserve forces. The average strength of the first class of the army of reserve was 44,215, and among them 333 deaths were reported, or in the ratio of 7·43 per 1000; and of the second class the strength was 6028, and the deaths 153, or 24·97 per 1000. The men of the first class were, with a few exceptions, under thirty-five, while the second class were almost all over forty years of age. The death-rate of the Militia, as shown in this return, was only 3·96 per 1000; of Yeomanry Cavalry, 4·46; and of Volunteers, 3·56; but there is good reason to believe that many of the deaths in these branches of the service are not reported, and are struck off the strength as "absentees."

DEATH BY HEART-FAILURE FROM STOMACH IRRITATION.

IF the means of masticating food be wanting, the first stage of the process of digestion cannot, of course, be performed, and this is in itself a great evil; but, as a recent fatal case has shown, actual perils to life from physical causes may arise, and perhaps become disastrously effective. By post-mortem demonstration, it has been proved that an accumulation of unmasticated food taking place in the stomach may so distend the stomach as to press upon and irritate the heart in such manner that, being in a morbidly weak or exhausted condition, its natural function may be arrested and death take place by syncope. It is a familiar fact that a greatly distended stomach may cause "palpitation" and other distressful experiences, and it is not in the least degree surprising to find that the excitation set up may be so aggravated as to produce fatal effects in a special state of the organism. But it is important to notice how this untoward ending is reached, because the attainment of this issue is only a question of degree in the disturbance. The operation from cause to effect is purely one of nerve action, and the *modus operandi* is either completely reflex, in which case the process is exhaustive as regards the particular centre affected, or partially reflex, the circuit, so to say, being broken at the centre, and the force of the peripheral excitation exerting an inhibitory influence on the cardiac or occasionally the respiratory centre. It seems probable that in certain cases there may be spasm of the muscular coat of the vessels of the heart (perhaps the coronary), or of the heart itself, producing either a condition resembling that which is supposed to obtain in some forms of "angina," or arresting the ventricular contraction in systole, or, it may be, by asystole, though this last-mentioned ending is perhaps more commonly reached by inhibition, as in another class of cases. When the excitation caused at the periphery is of a

Digitized by Google

nature corresponding with, and in some respects resembling, high tension of an electric current, the stimulus propagated along the afferent nerve trunk may so act on the centre, indirectly perhaps, as to interrupt its action. In this last event death will occur by arrest of the ventricular movement in diastole or arrest of the systole. Or the obstructive or exhaustive action may be upon the respiratory centre with seemingly "asthmatic" symptoms at the opening of the attack, in the course of which death occurs. Happily cases of a fatal issue from peripheral irritation of the nerves are not of very common occurrence; but this renders it the more desirable that those which do occur should be very carefully investigated. The subject of death from "heart disease" is one that greatly needs to be studied in the light of precise pathology.

SIR WILLIAM GULL.

As we announced last week, Sir William Gull was taken ill on Monday, the 10th inst., with right-sided hemiplegia. There was almost total paralysis of motion of arm and leg; tongue, eyelids, and facial muscles quite unaffected; intelligence not appreciably impaired. He was seized when out walking, about noon, and required to be assisted home. Twenty-four hours afterwards his motor power had largely returned; but there remained very considerable sensory paralysis of the whole right side, most marked in limbs and trunk, but quite observable in face, neck, and scalp. Since then, now nine days, his condition has been one of consistent gradual improvement. On the second day there was some slight disturbance, owing to sluggishness in the excretory functions, which, with a little assistance, soon righted itself. When visited by Mr. R. W. Irvine, M.B., of Pitlochry (under whose care he is), on Oct. 18th, at 4 P.M., Sir William was perfectly intelligent, clearly appreciating his own condition. He was taking light nutriment, and an occasional two-drachm dose of brandy-and-water. Functions acting well, and motor paralysis only slightly observable; sensory symptoms more marked. He is kept quite quiet, and all kind inquiries from friends, both by message and in person, are kept from him. The one feature in the case which has been the occasion of special anxiety has been a certain hæmorrhagic tendency. Last year he had hæmoptysis, and, later, profuse epistaxis. At the time of this occurrence he had slight and transient but marked hæmaturia, and in the light of this the brain lesion cannot escape being ascribed to a similar cause. For a week at least to come no attempt will be made to change the present system of treatment—namely, that of strict quiet, lightest diet, and the recumbent posture. It is hoped that by the end of next week, accidents excepted, the patient may safely sit up. He is nursed by his daughter and a nurse from Guy's Hospital.

MICRO-ORGANISMS IN THE AIR.

THE attention which Dr. Percy Frankland has devoted to the examination of the atmosphere for micro-organisms has resulted in a further communication to the Royal Society by himself and Mrs. Frankland, entitled "Studies on some New Micro-organisms obtained from the Air" (*Phil. Trans.*, vol. clxxviii.) This joint memoir is very creditable to the authors. It contains descriptions, with drawings, of the morphological characters of the microbes and their cultures. These include ten species of micrococci, twelve species of bacilli, two of saccharomyces, and an unnamed mould producing a dark-brown pigment. The specimens were obtained from various localities, and the descriptions embrace a few which have been sent to the authors from abroad. It is pointed out that, although from the fact of brilliant discoveries having been made in the etiology of infective diseases the greatest share of attention has hitherto been devoted to pathogenic micro-organisms, yet there is much to be profitably done in the investigation of non-pathogenic forms. Indeed, the part they play in the economy of nature may equal in importance that of the disease-inducing microbes, as instanced in the conversion of sugar into alcohol, the decomposition of nitrogenous matter with elimination of ammonia, the oxidation of ammonia to nitrous and nitric acids, and other natural transformations. There is certainly scope for much original research in this direction, and Dr. Frankland does well to pursue his inquiries into this comparatively untrodden ground.

OUR MILITARY PRISONS.

THE information given in the "Report on the Discipline and Management of the Military Prisons in 1886," regarding the health of the prisoners, is of the most meagre description. In the home prisons the percentage of hospital cases to the daily average of prisoners is stated as follows—Aldershot 18·0, Brixton 50·3, Chester 4·5, Gosport 10·4, Lancaster 0, Taunton 64·3, Glencorse 31·3, Cork 102·3, Dublin 17·7, Limerick 86·8. No information is given as to the diseases which came under treatment, nor is any explanation offered of the very remarkable range of sickness, from Lancaster, where no cases were reported, to Cork, where they exceeded 100 per cent. of the average strength. Nor are we informed whether any deaths occurred, except that in an "extract from the report of the medical officer" of Brixton prison it is stated that three died. The great range in the relative proportion of sick in the home prisons is the more remarkable when compared with the results from prisons abroad. These were—at Alexandria 53·1, Barbadoes 61·1, Bermuda 53·3, Cairo 47·7, Gibraltar 31·5, Halifax 105·5, and Malta 37·6 per cent. The very high ratio in the Halifax prison seems to call for inquiry on the part of the military authorities. With that exception, however, the range of sickness is not greater than might have been expected where the numbers are limited, and presents a striking contrast to that which is experienced—perhaps we should rather say is shown—by the returns of the home prisons; for it seems almost certain that the latter result arises from a want of uniformity in the system of admitting, or of reporting, the cases, rather than from a difference in the incidence of disease.

SEWAGE DISPOSAL.

LAST week the new system of sewage works at Henley-on-Thames was formally inaugurated. As a matter of fact, it has been in existence for some little time, but the ceremony to which we refer was delayed until it was assured that the machinery was in proper working order. Henley had been one of the districts which discharged their sewage into the Thames, and when this could be no longer permitted the corporation had to seek other methods for its disposal. The difficulty against which they had to contend was that of level, but this has been altogether overcome by the adoption of the Shone hydro-pneumatic system, which has been successfully used at Eastbourne. Situated in different parts of the town are ejectors which receive the sewage, and from which it is forced by compressed air into tanks distant about a mile from the houses and at a height of 180 ft. above the ejectors; here it is finally disposed of by irrigation, the solid matters being sold to farmers for manure. The advantages of this method are now well known; it relieves local authorities of all disadvantages which result from their town being situated at a lower level than the land to be irrigated; it is by no means costly, and sanitary authorities are no longer able to plead physical difficulties as reason for delaying the adoption of a proper system of sewage disposal. The cost to Henley-on-Thames has been about £18,000.

THE BELGIAN MEDICAL FEDERATION AND MEDICAL LEGISLATION.

IN an address recently delivered to the Belgian Medical Federation by the President, Dr. Van den Schrieck, the members were congratulated on the disposition which has begun to manifest itself amongst the medical profession to act on the defensive in the struggle for existence, which is every year becoming more and more severe, and a *résumé* was given of the endeavours made by the Federation to promote a Medical Bill in the Houses of Parliament which should be favourable to the interests of the profession. The points desired were, briefly, the reimposition of a degree in arts as a necessary qualification for entering on medical study; a central or State examination to be obligatory on all, whether possessed of university degrees or not, as well as on all foreign medical men wishing to practise in Belgium; and lastly, the suppression of the examination for the diploma of surgeon-dentist as at present arranged, dentistry to be treated as a surgical specialty. The Federation believed that if these alterations could be obtained the overcrowding of the profession would be stopped, and the character and attainments of its members raised. The President complains, however, that the nature of the changes asked for has not been properly understood in Parliament, even the medical members not seeing their way to urge them on the House. The committee of the House which has had to report upon the Bill is in favour of continuing to allow university degrees to form a qualification to practise, and giving the central examining board only such students to examine as have not taken a degree. The majority of the committee, too, are unfavourable to the proposal to make an arts degree obligatory. According to the Government Bill a complete five years' course in arts will be required, but not a degree. M. Thiriar, the eminent surgeon, seems to have been almost the sole member of the House who expressed views in accordance with those of the Federation, and consequently there seems but little hope that the Medical Bill, when passed, will satisfy that body. M. Van den Schrieck was able to announce that he had succeeded in arriving at a good understanding with the Pharmaceutical Association, notwithstanding the recriminations which have been passing freely of late between the doctors and the pharmacists, and of which we can hardly hope that we have even now heard the last.

THE LATE GEORGE FORDHAM.

THE death of George Fordham has called forth universal praise and commendation of the late jockey. His virtues were the more remarkable since his occupation threw him in the midst of temptation to yield to almost every base and sordid motive. It is saying a great deal of a man that nearly forty years' association with the turf left his character without a stain of dishonour. It is not necessary here to refer to his skill as a horseman. Fordham succumbed to phthisis, from which he had suffered for a long time. A contemporary draws attention to the fact that none of Fordham's relatives were subjects of consumption, and conjectures that the hard life incidental to his profession must have been the cause of his fatal malady. There is every reason to believe this to be the true explanation. Exposure to chills, profuse sweatings, and enforced starvation to get down weight, must in the long run tell their tale save in the most robust constitutions. Had Fordham come of a tubercular stock, he would probably have succumbed in his youth. Constable, and, if we mistake not, Kenyon—notable jockeys in their day,—fell early victims to phthisis, which only overtook Fordham with its "second wave," when he had just started on the downward curve of organic life.

THE CLINICAL SOCIETY.

THERE was a good attendance of members at the opening meeting of the winter session of the Clinical Society on Friday last, when Dr. Broadbent, the President, made a few remarks appropriate to the occasion. He said that it was unnecessary to exhort the members to increase their activity, for already there were numerous interesting papers in the hands of the secretaries. But he thought there would be some advantage to be derived from a bringing together on the same evening of cases of the same kind, or at least to group together cases illustrating similar points of practice, diagnosis, and treatment. In order to effect this purpose papers should be sent in soon, so that the secretaries might carry out the needed classification. In referring to the recently issued volume of the Transactions, the President said he believed it was the first time that the annual volume had been sent out before the opening of the winter session; it was an evidence of the great activity and energy of the secretaries, and would, he hoped, become a precedent. He remarked that the new volume contained the valuable report of the Committee on Charcot's Joint Disease, of which the President was Sir James Paget, and at the latter's special request he took the present opportunity of repeating how much the Society as well as the Committee were indebted to the personal work and intelligence of the honorary secretary, Mr. Bilton Pollard, for the completeness of the report and the promptness with which it had been drawn up.

A FUNGUS IN THE EAR.

DON JUAN SALELLES of Valencia describes in the *Revista de Laringologia Otalgia y Rhinologia* a case of a rare vegetable parasite, *aspergillus flavescens*, obstructing the external meatus of the ear of a young man. After syringing away a quantity of black matter, a smooth glistening substance of a dirty white colour with black spots was seen, which was the mycelium of the fungus studded with dark spores. All attempts to remove this with forceps provoked so much pain that they had to be given up. Glycerine was dropped into the ear, and in two days' time the patient returned in terrible suffering, the dark spores having been developed and forming a large mass. After this had been removed by syringing, alcohol and tannin were introduced, and at the next visit the mycelium was removed by the syringe, the membrana tympani becoming visible. In a month's time the fungus began to reappear, but was rapidly subdued by similar treatment, which was followed up by the daily instillation of dilute spirit for a short time. No further return occurred, and the patient entirely regained his power of hearing. The introduction of the fungus appeared to have been due to the use of some oil of sweet almonds, which had been kept for some time in an open bottle, and which the patient had been in the habit of dropping into his ear along with milk, as he suffered from otalgia.

CREMATION.

A FUNERAL of a somewhat unusual character took place on the 8th inst. at Birstall, a suburb of Leicester, when the cremated remains of the late Dr. Buck of that town were consigned to the earth. The church in which the service was held was decorated for a harvest festival, the burial service itself was choral, and the whole scene was remarkable for the absence of any of the usual outward trappings of grief and woe, though nothing could have been more impressive and solemn. The ashes of the deceased were carried by two friends in a small marble box. Dr. Buck was until two years ago physician to the Leicester Infirmary, and from his scientific attainments and zeal for his profession gave promise of a successful future career. Suddenly, to the

Digitized by Google

grief of all who knew him, he was struck down from the work of life by general paralysis. He had taken an active part in the promotion of the Leicester branch of the Cremation Society, and in accordance with his own wishes his body was cremated at Woking Crematory, and his ashes brought for burial to his home, as above stated.

MINERAL THREADS.

AN interesting paper on this subject by Mr. C. V. Boys, Demonstrator of Physics at the Science Schools, South Kensington, appears in the current number of the Journal of the Physical Society of London. Fibres of glass and other elastic materials are applicable to a variety of purposes in physical research, such as torsion balances, the fine lines fitted to the eye-pieces of optical instruments, the suspension of solids in the determination of specific gravities production of diffraction spectra, and the like. Spun glass has often been used for such purposes, but Mr. Boys shows that far finer and more perfect fibres can be obtained. He describes several ingenious modes of preparing such fibres, and has experimented with various materials. Melted resin, Canada balsam, and other viscous substances, when insulated and strongly electrified, shoot out threads of extraordinary tenuity but of little strength; but better results were obtained when light arrows, made of straw and attached to beads of melted glass, were shot from a powerful cross-bow. In this way perfectly uniform threads, $\frac{1}{10000}$th of an inch in diameter, are readily obtained. Still more remarkable results were obtained with rock crystal melted in the oxy-hydrogen blow-pipe. Some of these threads were invisible even with the highest power of a microscope, and must have been less than the $\frac{1}{100000}$th of an inch in diameter. Fine threads of rock crystal seem to be superior to all others. Their strength is equal to that of steel, and their elasticity is enormous. Most other threads are subject to the defect of "elastic fatigue"—that is, they do not return after torsion to their original position. This defect is not found in rock crystal, which will therefore be of great value in torsion apparatus, for which spun glass is useless. Spider lines are coarse compared with the filaments which can be obtained in this way, and the diffraction which they yield is said to be excellent.

TARNIER'S BASIOTRIBE.

TARNIER'S basiotribe, a somewhat complicated instrument which was described by him to the Paris Academy of Medicine in December, 1883, has recently been used in three cases in Professor Kufferath's obstetric wards in Brussels, with, it is stated, very satisfactory results, the application being made with great facility, no splinters penetrating the scalp, and the mothers being all able to leave the hospital on the tenth day.

PELLAGRA IN BADAJOZ.

DR. ANTONIO PONS SANZ, of Fuente de Maestre, writes to *El Siglo Médico* that several cases of pellagra have been observed in the province of Badajoz. During the spring of the year patches of erythema appear on the dorsum of the hands, and sometimes on the neck, which are attributed to the action of the sun. These are sometimes of a dark red, or even of a coffee colour, and are followed by desquamation. Afterwards diarrhœa and other gastro-intestinal troubles make their appearance, with a certain degree of jaundice. These are accompanied by nervous symptoms, amaurosis, want of co-ordination both in the movements and in the thoughts, and sleeplessness. Melancholia supervenes, and the patient not unfrequently commits suicide. As to the etiology of this disease, which is fortunately unknown in this country, being chiefly met with in Lombardy, and which is generally put down to eating diseased maize, Dr. Sanz observes that the food of the people in the province is very rich in proteids, and that they never eat maize, but that the victims of the disease have generally been addicted to drink; he has frequently observed, also, that they were the subjects of a "herpetic diathesis." The best treatment, in his opinion, is arsenic combined with the baths of Alange. By these means he has been able to overcome the nervous symptoms and the sleeplessness.

SCARLET FEVER IN LONDON.

THE number of cases of scarlet fever admitted into the hospitals of the Metropolitan Asylums Board during the week ending Oct. 14th showed a slight increase on the number of the preceding week, 246 and 277 cases being admitted during these two periods respectively. Huts have been erected in connexion with the hospitals at Hampstead, Homerton, and Stockwell, and the Winchmore Hill Hospital has been open a sufficiently long time for some of the patients to be discharged. In all probability the vacancies created by discharges and deaths will provide sufficient accommodation for those who may yet have to seek admission, and the existing hospital provision, with the huts, which are nearly completed, will be found sufficient for the requirements of the epidemic. This, it may be anticipated, will soon begin to decline. The first week in November should show a diminution in the number of admissions, and from that moment the number discharged should greatly exceed that of those received. On Tuesday morning the returns showed that the hospitals contained 2176 patients under treatment, of whom 2052 were suffering from scarlet fever, 113 from enteric fever, and 5 from diseases which were not infectious fever.

DILATATION OF THE STOMACH.

IMMEDIATELY following the psychological address with which Dr. Hughlings Jackson opened the new session, the Medical Society proceeded to the consideration of a common topic in practical medicine. Dr. Clifford Allbutt's paper on Dilatation of the Stomach was thoroughly practical, and was based on a wide experience. It will do good service in directing attention to the frequency with which the slighter, but not less intense, degrees of this affection occur. There is no doubt that under the guise of atonic dyspepsia many cases of this organic affection of the stomach have been concealed; and Dr. Brunton was quite justified in alluding to the curious neglect with which the affections of the muscular walls of that organ are treated, as compared with similar states of the intestine. Much was said of the advantages of Kussmaul's method of washing out the stomach, and perhaps too much was made of the objections offered by patients to the plan. Certainly all those patients who do practise it speak in praise of it; and a few months ago we received a long communication from a sufferer from this malady, who had been treated for a long time by other remedies without avail. At length he was fortunate enough to have this method prescribed him, and his enthusiasm in its behalf was an index of the vast relief it afforded. At the same time Dr. Hare did well to recall attention to the practical utility of a timely emetic, which is of value in cases where the affection has not proceeded too far. Wide as is the experience of Dr. Clifford Allbutt, it may hardly be equal to that of Professor Bouchard, who goes so far as to say that three out of every ten hospital patients have a dilated stomach ("Auto-intoxications dans les Maladies," 1887). Prof. Bouchard, moreover, attributes a multiplicity of ailments to this cause, on the ground that the products of fermentation in the organ have a toxic effect upon the economy. When we say that amongst the ill results of gastric dilatation this authority claims phthis-

Digitized by Google

chlorosis, many nervous disorders, skin diseases, albuminuria, rickets, and nodular rheumatism, it will be at once obvious that what some consider as causes he regards as effects. This, perhaps, was most strikingly shown in the case cited by Dr. Brunton of floating kidney complicating gastric dilatation. Dr. Brunton suggested that the gastrectasia in that case might depend on reflex irritation through the splanchnic nerves. His remark that movable kidney and gastric dilatation are not infrequently combined, and that it is the right kidney that is the one most commonly at fault, is strikingly corroborative of Bouchard's statement that 14 per cent. of this gastric affection are associated with movable kidney. He remarks that if the renal ectopia were the cause of the stomach trouble, the latter should be more frequent in women than in men, whereas the reverse is the case; and he attributes the former condition to mechanical displacement during temporary attacks of hepatic congestion, to which he says gastric dilatation specially disposes.

CHARING-CROSS HOSPITAL POST-GRADUATE COURSE.

THIS course of lectures is meeting with considerable support. Already 104 members have joined, and others are entering daily. What is, however, more remarkable even than the quantity is the quality of those who are joining. The members are in large and busy practice or hold important public appointments. They come not only from London itself, but from the country for thirty and forty miles round. With the increasing numbers the interest seems to grow. Questions are freely asked by the members at the close of the lectures, and answered by the lecturers. Every appliance has been provided for the class, and the whole staff as well as the governors and officials of the hospital have lent assistance to the movement. At the ward visits not only are cases shown illustrative of the lecture, but others that happen to be available are also made use of. Last Friday Mr. Barwell, F.R.C.S., showed seven typical cases of Lateral Curvature, and exhibited various appliances for remedying the disease. To-day (Friday), Dr. T. Henry Green, F.R.C.P., lectures on "Albuminuria."

HÆMATOLOGY IN THE NEW-BORN.

THE physiology of the blood of the new-born has not been adequately investigated, and we welcome, therefore, the observations of Silbermann, an abstract of which appears in the *Archives of Pædiatrics*, No. 45. Hofmeier had found that the size of the red blood-corpuscles was very variable; that their form was more spherical than in adults; that they showed no tendency to run into rouleaux; that the white corpuscles are often in greater proportion than usual; that the white corpuscles tend to accumulate in rouleaux, and that they are viscid, deliquescent, and easily destroyed. Silbermann confirms Hofmeier, and also shows in addition that the blood of the new-born contains *shadows*, which are certain delicate pale rings forming the stroma of red blood discs, the colouring matter having been removed. These bodies, first discovered by Ponfick, are found to be more abundant the more disturbed was the child's general condition during the first few days of life. Hæmoglobinæmia induced by this general disturbance does not always lead to hæmoglobinuria; but if it occurs, then, according to Schmidt and his disciples, the circulating blood will contain a relatively large quantity of fibrin ferment, red and white corpuscles having contributed to this result. Silbermann concludes from experiments on frogs, dogs, and puppies, giving results in the blood identical with those deviations met with during the first few days of life in the blood, urine, and liver of infants, that there was a free destruction of red corpuscles, resulting in the liberation of free hæmoglobin. Venous stasis and hyperæmia were found, and attributed to this consequent increase in the fibrin ferment, resulting from excessive destruction of the red and white blood-corpuscles. So it seems that the condition of the blood in the newly born predisposes to disease, and, in the presence of such conditions as asphyxia, omphalitis, syphilis, gastric and intestinal catarrh, and erysipelas, is likely to be of grave importance. It is supposed that the liver would convert the extruded hæmoglobin into bilirubin, and this is perhaps one of the natural functions of the liver, which, for aught we know to the contrary, may also aid in the destruction of the red blood discs as well as in the manufacture of bile. It is possible that this destruction and manufacture are one and the same process. The conclusions of Silbermann are worth repeating, and in this direction: The blood of the newly born shows evidences of imperfect stability in the variation in size of the corpuscles, in the presence of *shadows*, and in being rich in fibrin ferment. These results may be due to liberation of the hæmoglobin, and they may predispose to disease, since all morbid processes involving great destruction of albumen in the circulation are probably very dangerous to life.

THE NEW ENTRIES.

THE following is a list of the fresh entries for the current winter session at the various medical schools from which returns have been received:—

	Entire course.	Special classes.	Prelim. Scien.
University College	69	—	74
St. Thomas's	75	38	—
London Hospital	80	45	—
King's College	37	43	11
Middlesex Hospital	48	35*	1
Owens College	70	21†	37
Newcastle-on-Tyne	33	27	—
London School of Dental Surgery	22	—	—

* Including 7 dental. † Including 5 dental.

FEVER IN BURNRIGGS.

IN this village, which is near Carlisle, typhoid fever is stated to have attacked forty out of a total of some 130 inhabitants; and, as is so commonly the case, when once the disease and death occur, which it is a first duty of sanitary authorities and their officers to prevent, then we suddenly learn of polluted water, insanitary surroundings of houses, stench from nuisances, and just the very things that ought to have been dealt with long before they resulted in such mischief death. And now we hear that, amongst other things, a well has been cleaned. If the well has been polluted by reason of impurities in the surrounding soil, we do not see much good in cleaning it, and then proceeding to let the water into it again from the same source. The case of Burnriggs is typical of much so-called sanitation in rural districts.

RETRO-STERNAL PULSE.

THE clinical physician frequently palpates the supra-sternal fossa with the object of detecting abnormal pulsation in cases of aortic or innominate aneurysm, but to detect any very obvious pulsation is rather a rare occurrence unless an aneurysm is present. It is with some surprise and curiosity, therefore, that we read in the *Revue Générale de Clinique et de Thérapeutique* of Oct. 13th, No. 35, that M. Maurel of Cherbourg has 200 times out of 500 cases detected a pulsation by depressing the integuments above the supra-sternal notch, with the object of palpating the region of the posterior surface of the manubrium. This phenomenon is believed to be due to pulsations of the left

Digitized by Google

innominate vein, especially in cases of insufficiency of the tricuspid valve and of excessive venous tension, whether from dilatation of the aorta or not. The author has specially noted this retro-sternal venous pulse in cardiac affections and in the early stage of typhoid fever. M. Cuneo regards this pulse as a sign of aortitis, and aortitis may be of malarial origin.

PHYSICAL CONDITION AND PHYSICAL PUNISHMENT.

EXPERIENCE has abundantly proved that for some offences corporal punishment is a corrective of no small value. The rascals who are periodically sentenced for assaults against the person are known to dread the lash even more than the rigorous discipline of prison life and the forced exercise of prison labour. It is to be hoped that no mistaken philanthropy will rob the law-respecting of that friend of justice, the cat-of-nine-tails. Equally suitable for a younger generation of offenders is the birch, by which authority vindicates its title to their obedience. The Home Secretary is, however, of opinion that this form of chastisement is in some danger of being overdone. It may be so. There are in every social grade feeble children who stand physical punishment badly. It is well to make provision for such, and the recommendations to the Commissioner of Police that the weight of the birch ought to bear some proportion to the age of the child, and that a medical veto should be available to protect the latter if evidently weak. Indeed, we must insist that in all cases of the infliction of corporal punishment on children the opinion of a medical man should always be taken. Sir Charles Warren is, we understand, making inquiries into the subject with a view to determining what modifications are possible in this form of punishment. It must not be forgotten that by far the greater proportion of criminals, young and old, are town-bred, and that the conditions of life in the back slums of a city, in the presence of abounding dirt and discomfort, and the absence of proper food, fresh air, and exercise, do not tend to foster either health or endurance; consequently, while we deprecate the inconsiderate zeal of those who would forego the use of corporal punishment altogether, we readily admit the reasonableness of the precautions above mentioned.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Señor Don Juan Garcia de la Linde, a well-known Spanish writer and clinicist.—Dr. Don Rafael Lasso de la Vega y Chinchon, a well-known practitioner in Seville.—Dr. Don Enrique Amell y Robert, a Barcelona laryngologist.—Dr. Don José Maria Fernandez y Cárceles, a distinguished practitioner in Madrid.—Dr. O. S. Jensen, the anatomist of Christiania.—Dr. Karl Haller, Emeritus Primararzt of the Vienna Hospital, at the age of seventy-eight.—Dr. Emil Szöts, director of the Clausenburg Hospital. — Professor Tsêakovski of Kharkoff, who has recently made a number of valuable observations on the Siberian sore.

NEPHRITIS IN SCARLATINA.

DR. HAZE states, in a report on the scarlet fever cases treated in the Elisabeth Children's Hospital in St. Petersburg during last year, that out of 145 such patients, 19, or 13·1 per cent., suffered from nephritis. This is a rather smaller proportion than the average of several years, tending to show some diminution in the number of kidney affections consequent on scarlatina; for during the years 1871 to 1886, out of 875 scarlet fever patients, 135, or 15·7 per cent., were found to be affected with nephritis.

THE ILLNESS OF THE ROYAL PRINCESSES.

WE are in a position to state that the Royal Princesses of Wales, who are suffering from an attack of measles, are progressing favourably. The disease is, we understand, in each case, pursuing a mild course, and an uninterrupted progress towards recovery may be confidently anticipated.

POISONING BY TOLUYLENDIAMINE.

IN poisoning by toluylendiamine, if the process be a lengthened one and lasting several days, Kiener and Engel have found that the urine, besides being jaundiced, and sometimes yielding hæmoglobin, likewise contains pigment granules, having iron in their composition, and probably derived from hæmoglobin ultimately. The ferruginous pigments deposited in the organs of the animals poisoned by sulphide of carbon led them to experiment on the effects of toluylendiamine. They believe that the iron pigments are more constant indications of the destruction of red blood discs than is either icterus or hæmoglobinuria. In rabbits on which experiments were made, icterus was always wanting; hæmoglobinuria was only observed once, but twice the pigmentary granulations were detected in the urine. In dogs the signs of destruction of the blood globules were not always present.

A WELL-FOUNDED COMPLAINT.

A CORRESPONDENT has directed our attention to the condition of waterclosets in railway stations. We have no hesitation in saying that many of them are a disgrace to those who are responsible for their control. In many instances they are without any external ventilation, and are allowed to be dirty to an extent that shocks those who are compelled to use them. The subject is one that urgently requires the attention of railway directors and of medical officers of health. Bad as they are, they could many of them be improved by the provision of openings for ingress and egress of air, and certainly no difficulty would be found in maintaining them in a reasonable state of cleanliness. If other grounds for urging this matter upon railway officials are required than those of decency, we may plead the serious detriment to health which occasionally results to travellers from their inability or unwillingness to enter offensive premises.

METROPOLITAN HOSPITAL SUNDAY FUND.

WE are glad to be able to record that the total amount received at the Mansion House towards this year's Fund is now £40,433 3s. This sum exceeds the total of any previous year. The financial year closes on October 31st.

CIRCULAR WARDS.

WE hear that Dr. C. Lange and Dr. Oscar Bloch, two well-known physicians of Copenhagen, are now in this country for the purpose of visiting and obtaining a practical acquaintance with the system of circular wards for hospitals. They will inspect the Miller Memorial Hospital at Greenwich, the Burnley Hospital, and the newly completed hospital at Hastings; so that Professor Marshall's prophecy, that this last-named and latest realisation of his idea will be visited even by foreigners as well as by our own countrymen anxious to examine into the merits of the circular system, has speedily become true. Dr. Lange is the active and courteous physician who was secretary to the International Medical Congress at Copenhagen, and, together with Dr. Bloch, has been appointed on a committee of inquiry to report on hospital construction, in view of the intended erection of a new hospital at Copenhagen.

SIR MICHAEL HICKS BEACH.

IT will be gratifying to the friends of Sir Michael Hicks Beach to learn that the health of the right honourable gentleman has been considerably improved by the change, rest, and treatment he has experienced. At a consultation recently held by Dr. Robson Roose and Mr. Critchett, it was found that the eyes had been considerably benefited, and that the general condition was such as to warrant the belief that, with due precaution, Sir Michael may safely resume his political duties. This result has fully justified the views expressed last March by his medical advisers.

THE SCHOOL BOARD AND SCARLET FEVER.

ACCORDING to a recent police-court report, it would appear that School Board visitors even summon parents whose children are absent from school because they are either themselves ill of scarlet fever or are living in a house where the disease prevails. Nothing could well tend to bring compulsory education into greater disrepute, and visitors should always be required to satisfy themselves that there is no infectious disease in the house of absent pupils before they proceed to enforce attendance.

LÆVO-ROTATORY SUGAR IN THE LIVER.

DR. PANORMOW has found in the liver a sugar-like substance which possesses lævo-rotatory power. He has not succeeded in isolating it. His observations, however, tend to show that Seegen was wrong in thinking that all the sugar in the liver is dextrose.

FOREIGN UNIVERSITY INTELLIGENCE.

Erlangen.—Dr. F. Hermann has qualified himself as *privat-docent* in Anatomy.

Marburg.—Dr. Hans Strahl has been nominated Extraordinary Professor.

Prague.—Dr. A. Obrzut has been granted the title of *Docent* in Pathological Histology in the Bohemian Faculty.

Würzburg.—Dr. Matterstock has been appointed to the Professorship of Medicine, vacant by the death of Dr. Geigel. Dr. Lehmann, assistant in the Hygienic Institute in Munich, has been appointed to lecture on Hygiene, which had been included in the deceased professor's duties. He is to have the title of Extraordinary Professor.

ON the 13th inst., Messrs. Harries jun. and Blakiston, the house-surgeon and assistant house-surgeon to the Salop Infirmary, were shooting rabbits about three miles from Shrewsbury, when Mr. Harries' gun accidentally went off and the charge struck Mr. Blakiston, who was about ten yards distant. The shot entered directly over the sacrum, within an area of six inches, and too deep for extraction. We are sorry to add that symptoms of peritonitis have since declared themselves, and Mr. Blakiston's condition is extremely critical, although during the past three days more hope of his recovery has been entertained than in the earlier part of the week. His temperature and pulse are low, and there is less tenderness and tympanites. Much sympathy is felt for both the sufferer and the accidental inflicter of the injury.

AN alarming outbreak of fever, resulting in a large number of deaths, is reported to have taken place among the British troops stationed in the Kazr-el-Nil barracks at Cairo. The immediate cause is said to be the infiltration of the Nile water in the barrack square. Much regret is expressed that the men were not removed from the infected building and placed under canvas.

PROFESSOR KIRCHHOFF, the celebrated scientist and discover of the spectrum analysis, died at Berlin on the 17th inst. He was born at Königsberg in 1824, and it is now exactly forty years since he went to the University of Berlin as a *privat-docent*. In 1850 he was called to the Chair of Physics at Heidelberg, where, in company with Bunsen, he carried on those researches which at last resulted in the discovery that at once raised him to the first rank of natural philosophers, and opened a new era in the history of chemical analysis. In 1875 Professor Kirchhoff went back to Berlin, where he was made a member of the Academy of Sciences.

DR. B. P. ROOKE, who died at Redhill on the 8th inst., at the advanced age of eighty-six, belonged to the old East India Company's Medical Service, which he entered as assistant surgeon in 1826 on the Bombay medical establishment. He became in due time head of the department, and retired in 1862 as Principal Inspector-General of Hospitals. He served on Lord Keane's staff throughout the Afghan war in 1838-39, was present at the taking of Ghuznee, and obtained a medal. Dr. Rooke was honorary physician to the Queen.

MR. RICHARD BERRIDGE, late of Ballynahinch Castle, Galway, Knowlehall, Bridgwater, and the Cedars, Putney, has by his will bequeathed the sum of £200,000 in trust "for the advancement and propagation of education in economic and sanitary sciences in Great Britain."

THE Government inquiry into the sanitary condition of Bethnal-green was resumed on Wednesday last, when Mr. Shirley Murphy and Mr. Cubit Nichols, the commissioners, commenced their investigations of the state of some of the poorer parts of the district.

THE *London Gazette* of Oct. 18th announces the appointment of James Cecil Phillippo, Esq., M.D., as a Member of the Privy Council of the Island of Jamaica.

A MEETING of the General Medical Council will be held on Tuesday, November 22nd.

PERSONAL REMINISCENCES OF THE LATE PROFESSOR VON LANGENBECK.

WE have received the following sketch of the great surgeon, which has been furnished us by the two surgeons intimately acquainted with him during the period referred to.

It was in the early part of December, 1870, that the writers of these brief reminiscences became intimately acquainted with Professor and General-arzt von Langenbeck. It was in Orleans, and at the period of the Franco-German campaign when the active operations of war were centred in and concentrated around this city. We may briefly recall the state of Orleans at this period. The city had been captured by the Bavarians on Oct. 11th, after four days' very heavy fighting; was recaptured by the French after the battle of Coulmiers on Nov. 9th, when General von der Tann, commanding the Bavarian army, effected a strategic retreat in face of a very superior force, and wisely fell back on the main body of the German army, now closely besieging Paris. Meanwhile, Metz had capitulated on Oct. 25th, and thus set free the armies of Prince Frederick Charles and the Grand Duke of Mecklenburg. These armies, advancing by a series of rapid marches, effected a junction with Von der Tann, when a general advance was again made on Orleans, the three armies marching in separate bodies, the whole forming a huge horseshoe line some sixty miles in extent, its extreme right resting upon Pithiviers, and its left upon Bellegarde and Montargis. After some very heavy fighting

Digitized by Google

the city was finally reoccupied by the Germans on Dec. 5th. As a result of this continuous fighting, the city had become crowded with wounded of both armies, and at this date was a very charnel-house. Churches, barracks, schools, convents, railway station, a large number of private houses, and indeed every available building, had been converted into an extemporised hospital. Every preparation had been made for the reception of the wounded, and it was fortunate that this was so, for the severe fighting of the few previous days had made a further demand on the resources of the place. The nurses of the various German and French nursing aid societies, assisted by the Sisters of the convents and by a large staff of lady volunteers, had by this time become familiarised with their work and efficient in their duties. Luckily there was no lack of surgical appliances and dressings, for the volunteer societies of various nationalities, recognising the urgent necessities of the wounded, and regarding Orleans as the base for further military operations, had richly equipped the hospitals, permanent and extemporised, with all needful material. This condition of preparedness put the city more in the position of a capital endowed with permanent hospitals, and permitted of the surgical work being performed in a more scientific, careful, and accurate manner than usually obtains in the history of warfare. The surgical staff was now considerable, for, in addition to the large number of German surgeons, and a few French army surgeons, nominally prisoners, there were volunteer ambulances officered and equipped by men from England, America, Switzerland, Holland, and other countries. At this period Langenbeck arrived amongst us with the head-quarters staff of the 3rd Prussian Army. We, as Englishmen, were much impressed by the marked deference everywhere shown to him by his professional brethren of all ranks and ages, whether by his countrymen or surgeons of other nationalities. From early morning until late in the evening his services were in constant request, both as consultant and operator; he was in demand everywhere, and did not spare himself even at his age. Ever careful, ever jealous of the interests of others, and more especially of juniors, he would only consent to perform operations at the special request of the particular surgeon in charge of the case. His especial skill in the performance of subperiosteal resections was so well known that he was most frequently called upon to perform them. More especially in connexion with these operations his extraordinary capacity as a clinical teacher asserted itself, and soon a numerous and attentive clinique followed him. Our special and peculiar intimacy with him dates from one of these most interesting cliniques. He was performing a subperiosteal resection of the shoulder joint, when, the knives at his disposal being considerably the worse for wear and tear and the rough usage to which they had recently been subjected, turning round to his assistant, he said, "Dieses Messer ist nicht scharf." Fortunately we were able to offer him an English-made scalpel in good condition, an attention with which he was much pleased, and which he never subsequently forgot; for during war time, when instruments are in constant use and there is no one skilled in sharpening, or indeed anything on which to sharpen them, a keen knife becomes of almost priceless value.

Langenbeck, deeply impressed with the importance of the many debatable and moot points in military surgery, facts towards the elucidation of which were constantly coming under the observation of the surgeons around him, urged the desirability of establishing a Surgical Society; it was mainly owing to his intense activity and great personal influence that a "Militair-Aertzliche Gesellschaft" was organised, which held its first setting on Dec. 23rd, within eighteen days of the occupation of the city by the Prussians. Professor von Langenbeck was unanimously elected its president, and Dr. Gaehde its secretary. At its first sitting it was resolved: "That its meetings should take place every week at half-past eight on Wednesday and Saturday evenings; that all German and foreign colleagues be invited to take part in the proceedings, and that each be allowed to speak in his mother tongue." Professor von Langenbeck's introductory address was on the subject of Prophylactic Tracheotomy in cases of Gunshot Injuries of the Larynx, even though there might be no urgent dyspnœa. He was induced to select this subject from the fact that he had seen in the action near Pithiviers, a few days previously, a dragoon who had been wounded in the region of the larynx suddenly die from asphyxia, due to œdema of the glottis, though apparently not dangerously injured; it was a subject in which he had long taken a deep interest, his experience dating as far back as the year 1848. Various other cases were related by those present, amply confirmatory of Langenbeck's experience. Amongst many interesting subjects of discussion the following occur to us:—"Gunshot Injuries of the Hip Joint, and their treatment by Resection"; "Traumatic Infiltration, Hæmorrhagic and Inflammatory"; "Gunshot Injuries of the Knee Joint, and their Conservative Treatment"; Gunshot Fractures of the Thigh, with relation to their early and late treatment and modes of transport"; "Pyæmia"; "The Relative Effects produced by Rifle Bullets"; "Ligature of Arteries"; "Wounds of Pelvic and Abdominal Viscera"; "Hospital Gangrene"; "Epidemic Cerebro-spinal Meningitis"; "On Methods of Amputation." In the discussion on this last subject Dr. Gaehde remarked upon the conservation of the periosteum and upon the advantage of making periosteal flaps as a protective cover for the end of the bone, and as considerably diminishing the risks of osteo-myelitis and of sloughing of the flaps. Various specimens of bullets were brought forward by Dr. Müller as affecting the question of explosive charges, constituting a breach of the Convention of St. Petersburg. Thus it will be seen that the proceedings of the society embraced a wide range of subjects; the discussions were supplemented and illustrated by pathological specimens, drawings, and bullets altered in form by contact with various parts of the body. These enjoyable meetings, continued twice a week until the end of February. Amongst the best remembered names of those attending the society were Dr. Loeffler, Dr. Müller, Dr. Bock (a former assistant of Dr. Frerichs of Berlin, who soon after succumbed to typhoid fever), Dr. von Montmollin of Geneva, Dr. Senator, Dr. Metzler, Dr. Fritsch, Dr. Fuchs, and Dr. Landsberger. We must not omit to mention the great personal share that Langenbeck took in the proceedings of this society, nor that its success was mainly due to the enthusiasm evoked by his presence and example.

It is difficult to estimate the actual number of subperiosteal resections which Langenbeck performed during his stay in Orleans; a day rarely passed for a period of many weeks without his performing an operation on one or other joint. Though often at this time and at a later period conversing with pleasure and pride on the large number of successful resections that he had performed in his various campaigns, he never forgot to award a due meed of praise to Heine, who was the first to demonstrate their value on dogs; nor to Flourens and Ollier, who were the first, or amongst the first, to perform these operations upon the living subject. It must not be supposed from the number of operations performed that Langenbeck was a mere operator, for he never failed to inculcate by precept and example the essential importance of careful after-treatment, continued even for long periods; and was most particular in recording the final result of all cases on which he operated whenever it was possible for him to do so.

At the conclusion of the war, in obedience to the command of the Emperor, Professor Langenbeck made a tour of inspection of the principal hospitals in Germany, permanent and temporary, occupied by the wounded. He very kindly invited us to accompany him as his assistants—an invitation that we gladly and gratefully accepted. Commencing with Strasburg, we gradually made our way to Berlin, visiting, amongst other places, Carlsruhe, Heidelberg, Stuttgardt, Mannheim, Darmstadt, Frankfort, Homburg, Wiesbaden, Mayence, Ems, Rüdesheim, Bingen, Coblenz, Bonn, Cologne, Elberfeld, Düsseldorf, &c. We have before said that Langenbeck was not a mere operator, and this journey with him gave us the opportunity of seeing the extreme interest that he took in his final results. The minuteness and care with which each case was examined and noted proved Langenbeck to have sympathies and interests far beyond the mere mechanical act of operating. It was during this tour that Langenbeck collected much of the material which, later, formed the basis of his Chirurgische Beobactungen aus dem Kriege, Ueber die Schussverletzungen des Hüftgelenks, Ueber die Endresultate der Gelenkresectionen im Kriege. This journey had an especial charm for him, for in almost every hospital in every town he found either an old pupil or assistant glad to welcome him, and whose clinical successes, as seen by us, testified to the excellent teaching of his old master.

Although cheered by the hearty welcome which greeted

Digitized by Google

him on all sides, whether by old pupils now occupying prominent positions, by friends of all ranks of society, including numerous Royal personages, who showed him the highest consideration, yet to us, his constant companions, there was the shadow of his great grief, which gradually deepened as he approached his home in Berlin; for it will be remembered that he had lost a favourite son, a promising young officer of the Rifles of the Guards, who had fallen at Gravelotte while gallantly leading his company. Almost immediately after his arrival in Berlin he resumed his hospital duties at the Royal Universitäts Klinikum, where his clinic was crowded. He was soon overwhelmed with private practice; in addition to the number of patients who had awaited his return, large numbers of wounded officers were daily flocking to Berlin to have the benefit of his skill and advice, many of them with wounds of the face requiring more or less repair by plastic operation, a class of cases in which he took especial interest, and in which he pre-eminently excelled. In addition to his private work, he held a class of operative surgery on the dead subject, which was largely attended by students and military surgeons returning from the front; this class was held from 6 A.M. to 8 A.M. The remainder of the morning was devoted to consultations and operations in private. He was due at his clinic at 2 P.M., but arrived half an hour before that time for the purpose of receiving in his private room the visits of private friends, military surgeons, medical men with special introductions, and arranging with his assistants (at this time Drs. Busch, Trendelenburg, and Bose) the order in which the various cases sent to him should be brought forward in the clinic. At 2 o'clock precisely he entered the theatre, wearing a specially made tightly-fitting coat of black material (scrupulously cleaned for each day); here he examined students most carefully, demonstrated the cases, and performed any necessary operation. We know of no other hospital in Europe where richer pathological and operative material was at the disposal of any one single surgeon than that over which the late von Langenbeck then presided.

He was fluent of speech, possessed of sympathetic voice, great charm and impressiveness of manner, with a most intimate knowledge of every detail of his subject, and produced an effect upon his hearers which no pen can adequately describe. As an operator he was in the very first rank, original, bold without recklessness, and of great anatomical knowledge. Of endless zeal and untiring industry, Langenbeck combined in himself all the elements which go to make a good surgeon and teacher, and there are few men who have left a deeper impress on the surgery of their time, not merely by reason of his own individual work, but indirectly through those who were his pupils, and are now so worthily occupying leading positions in the Universities throughout Germany. An aristocrat in appearance, manner, and feeling, modest in demeanour, the trusted friend and councillor of his Sovereign, revered and esteemed by all classes of society, the friend of all and enemy of none, his country will long mourn a loss which will also be felt throughout the empire of surgery.

THE HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.

The new Hastings, St. Leonards, and East Sussex Hospital, situated at White Rock-place, Hastings, was formally opened on the 13th inst., by Mr. Wilson Noble, M.P., in the presence of a large and influential gathering.

The new building occupies the site of the first structure, finished in 1841. It stands immediately opposite the pier, facing the sea, in a warm and sheltered position, and is externally of somewhat striking architectural appearance, being built of red brick, with white stone dressings, and presenting on either wing two massive circular wards, with open-air balconies on top, and central ventilating and chimney shafts. The structure is in four storeys, the basement being utilised as store-rooms, larder, heating chamber, &c., and the entire upper floor being for the domestics and female staff of nurses, containing kitchen, pantry, and offices. All the cooking is done by gas, and the building is heated throughout by hot water. The communication is by electric bells. The ground floor and the second and third floors contain the wards for patients and various apartments for the administration and staff. The accommodation is designed for seventy-two beds, and five cots for children, the total area covered by the new hospital being about 210 feet frontage, and from 50 ft. to 60 ft. in depth. Three circular wards in the eastern wing give on each floor accommodation for twelve patients, and on the western wing there are two similar wards with twelve beds in each. All the newest appliances for the comfort of the patients and the convenience of the domestics have been adopted by the committee of the hospital, and supplied by the builders. The total cost of the structure is about £19,500, and the debt before the day of opening was £3700, which by the collections and subscriptions on the 13th inst. has been reduced by £600. The memorial stone of the new building was laid by Lord Brassey, on Aug. 24th, 1886. Entering the building by the main entrance, through the outer porch, a small entrance hall is reached. In front of this is the main staircase, and close to the staircase is a lift for taking the cooked food from the kitchen to the wards, and other domestic uses. The central portion of the structure on the ground floor is devoted to the administrative department. On the west, facing the front line, is the committee room, a noble apartment, well lighted. Adjoining is the secretary's office. Beyond is the reception hall for the out-patients, with rooms for the physicians and surgeons, and a consulting room. Close to the reception hall is the dispensary, with the dispensing table. All these rooms are admirably adapted for their purpose, and plainly furnished. On the east side of the staircase, on the same floor, is a splint room, a duty room for No. 1 ward, and some cupboards, &c. The apartments for the house surgeon (a bed and a sitting room) are on this floor, facing south. No. 1 ward occupies the ground floor, on the eastern wing, and a description of it applies to all the circular wards in the establishment. Its diameter is 41 ft. and its height 13 ft. 6 in., the ceiling sloping slightly upwards towards the centre, with large windows, and has floor space for twelve beds. Three fireplaces occupy three sides of the sexangled shaft which rises through the various circular wards, built so as to provide ventilation as well as to convey away the smoke from the fires. The heads of the beds are placed to the wall. In the rear of the ground floor, and detached from the main building, is a casualty room for the reception of accident cases; also an operating room. These rooms are reached by the exterior passage from the front street or the rear entrance. There is also a mortuary and a post-mortem room, with closets and other offices for the use of out-patients. On the second floor the south side is occupied with the matron's apartments (bed and sitting room), three small wards, and a men's day room. On the north side is the duty room, linen room, and others. At each end of this floor is a circular ward, approached by an open arcade, thus detaching the ward, when desired, from the main building. This arcade leads to an open-air balcony, facing south, for patients to take the air in warm weather. Opening out of the circular wards, and to the rear, are closets, bath room, &c. A spacious corridor runs along the structure from east to west, connecting the wards at each end. On the third floor is No. 4 ward (east end) and No. 5 ward (west end), fitted up and designed similarly to those below. Close to the entrance to these wards, at each end, is a staircase leading to an open-air platform on the exterior top of the wards, where the patients may rest and walk about, enjoying the sea breeze and the animated scene along the esplanade. On these platforms, in the open air, are five screened seats, placed against the chimney shafts, and well covered in, so as to give protection from wind and rain. The women's day room, the nurses' bedrooms, and the children's ward (for five or six cots) are on this floor. On the fourth floor is the kitchen department. The apartments for the servants and nurses are also on this floor.

Mr. Noble having formally declared the building open,

Professor MARSHALL, F.R.S., President of the General Medical Council, said the English people were proverbially known as a practical people, but yet they had there evidence that they were not altogether destitute of a feeling for the ideal, because only a short nine years ago a circular hospital existed only in idea. In 1878 he had published an original paper on this subject, and now the people of Hastings and its neighbourhood had joined with many others in endeavouring to carry out his suggestions. Here, for a second time in England, a large hospital with circular wards was now opened; and here, in the realisation of his plan, pub-

Digitized by Google

tical ladies and gentlemen asked him to come forward and assist them in opening this actual building. The idea of a circular hospital was founded, first of all, on a geometrical notion that would commend itself to everyone. A circular hospital, in the first place, with a certain "run of wall"—to use an architectural phrase—gave them a larger enclosed space to deal with than any other form which might be conjectured. If they converted this "run" into a square, they had a smaller area, and they could not get the same amount of space within a triangular or any other form as in a circular construction. What did that mean? It meant that they had included a certain larger amount of air, and, as that was the very life breath of a good hospital, they had, by adopting the circular form, more air for their sick patients to breathe than they could have in any other form of building included within the same amount of wall. Then, again, the advantage of a circular ward was that it fell away from all surrounding objects, and they had a sweep of air around their building. Round a circular building they would have a freer circulation of air than they would about a square one. Next, in regard to light: in a circular ward they had light all round; and light, as they knew, was one of the most beneficent agents in nature. It had been shown by Dr. Downes, the medical officer of Colchester, that if you placed fluid in glass tubes for the development of bacteria, and in one case covered up the tubes, and in the other left them open and exposed to the sun, whilst the covered ones would develop innumerable bacteria, the others would scarcely develop any, or none at all. Abundant light, therefore, was essential in every ward. They might equal, but they could not possibly exceed, the quantity of light they could get into a building by the circular form. He did not say they could not accomplish a similar amount of light in a rectangular ward, but a circular ward received the light, as a matter of course, from every point, whether direct from the sun or reflected from the clouds. So much, then, for light. Then came the question of ventilation, which was one of the great problems of the scientific man, of the physician, and of the architect. Was there a public building in this country in regard to which they would get everyone to agree that it was a perfectly ventilated building? He knew of none, but the nearest approach to it was in the circular ward, for the simple reason that it was exposed at all points, and whichever way there was a pressure of air, they were sure to receive the advantage. The circular form, without any contrivance or thought of intricate arrangements, distributed the wind, and weakened and modified any great pressure. From without, the currents of air entered at different angles, and with different force at different windows; whilst within, these converging streams were deflected from the internal curved surface and caused whirling movements, the tendency of all being towards the ventilating openings in the centre, to which they were conducted by a slight coving of the ceiling in an upward direction. For ventilating purposes, therefore, the building needed but little subsequent thought; it required certain openings, and the whole process went on automatically and gently by night and day without any complicated contrivances. On the question of artificially heating a ward, it was easy to understand that with a central or a circumferential source of heat, or with both, a circular space could be more equably warmed than an oblong one. Then, again, there was something pleasant about a circle, even in internal appearance and aspect. For several reasons a bay window was a more agreeable thing in a house than a flat one. In a long parallelogram patients were placed near their opposite neighbours, and were doomed to look out upon the same buildings, the same smoke, a constant similarity, a sameness of aspect; whereas in a circular ward, they were further apart, and, if they simply turned their heads, were struck with something fresh and genial. Lastly, let them take administration. Could anything be better than a circular ward in that respect? They had the patients ranged round, and the attendants moving in the centre. Everyone could be seen and heard; the conveyance of medicine and food, of apparatus and dressings, was facilitated; and that was an obviously incidental merit. As he had said, he was addressing a practical people, and therefore they would ask if he could give them any instance of success in regard to the building or working of a circular hospital? The largest building of the kind in England was at Burnley, in Lancashire, and there, after twelve months' experience, everything was found to answer admirably. In support of this statement, he would read three letters which he had received from his friend Dr. Brown of that busy and populous place. He could only say, in conclusion, that he wished success to this undertaking. It would give him extreme pleasure now and then to come and visit the hospital, and see how they were getting on. He prophesied that it would be much visited both by their own countrymen and by foreigners interested in hospital construction. He was delighted to have had the opportunity of being present that day, and of encouraging them, after all the troubles of which he had heard. Excepting here and there little modifications such as experience would dictate to them, they had a fine building, which would do well the work which was required of it. He should wish to add that great credit must be awarded to the enterprise and adaptive ingenuity evinced by the architects, Messrs. Young and Hall, and to the watchful care of Dr. Bagshawe and his fellow committeemen.

Following the ceremony at the hospital, a public luncheon, which was largely attended, was served at the Royal Concert Hall. At this meeting the Bishop of Chichester, with Professor Marshall's concurrence, spoke warmly of the advantages of the open balconies in front of the building, and of the platform with its sheltered seats on the top of each circular tower.

CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

FROM the Calendar of this institution, which has just been published by the Council, it appears that 20,067 qualified practitioners are now inscribed in the College roll—viz., 1116 Fellows, of whom 664 obtained this distinction by examination, 8 were elected as Members of twenty years' standing under Section 5 of Charter 15 Vict., and 2 are *ad eundem* Fellows. There are 17,377 Members and 957 Licentiates in Midwifery (the examination for this licence has been suspended for the last twelve years). The Licentiates in Dental Surgery number 617.

The examiners in Elementary Anatomy and Physiology, appointed in conjunction with the Royal College of Physicians under the Scheme for an Examining Board in England, are elected annually. There have been four examinations during the past year, 685 presenting themselves in Anatomy and Physiology, of whom 528 passed in both subjects, 87 in Elementary Anatomy, and 34 in Elementary Physiology; 36 candidates were referred in both subjects; 64 candidates presented themselves in Elementary Anatomy, 56 of whom passed and 8 failed; 86 presented themselves in Elementary Physiology, of whom 68 passed and 18 failed. The fees derived from candidates for this examination amounted to £3940 13*s.*, the examiners receiving in fees £564 15*s.*

The examiners in Anatomy and Physiology, appointed in conjunction with the Royal College of Physicians under the scheme for an Examining Board in England, are elected annually. They have conducted the "Primary" Examination under the old regulations, as well as the Second Examination of the Examining Board, and have held during the year four examinations, at which 937 candidates presented themselves for examination in Anatomy, of whom 558 passed and 379 were referred; 854 candidates presented themselves in Physiology, of whom 515 passed and 339 were referred. The fees paid for these examinations by candidates amounted to £4713 19*s.* 6*d.*, the examiners receiving in fees £2064.

The Board of Examiners in Anatomy and Physiology for the diploma of Fellow consists of nine members annually elected by the Council from the Fellows of the College, and has held during the past collegiate year two examinations. At these 142 candidates presented themselves, of whom 75 passed and 67 were referred. The fees paid in connexion with these examinations amounted to £1065 15*s.*, the Board receiving in fees £639.

The Court of Examiners consists of ten members elected by the Council from the Fellows of the College (all of whom, however, are members of the Council except Mr. John Langton, Mr. T. Pickering Pick, Mr. H. G. Howse, and Mr. W. M. Baker). They have conducted the Third or Final Examination of the Examining Board, as well as the Pass or Final Examination under the old regulations, and the Pass or Final Examination for the Fellowship. During the year the Court has held two examinations for the Fellowship and

Digitized by Google

five for the Membership; at the former there were 58 candidates, 31 of whom passed, 18 being referred for one year and 9 for six months. For the Membership there were 1083 candidates, of whom 267 obtained their diplomas, and 302 passed in surgery only; 143 were referred for three months, 325 for six months, 23 for nine months, and 22 for one year. The fees paid to the Court of Examiners amounted to £6329 16s.; the fees paid by the candidates reaching £12,845 9s. 6d.

The Board of Examiners in Dental Surgery has held three meetings for the examination of 37 candidates, 28 of whom received their diplomas. The fees paid by them amounted to £294, of which the Board received £88. 4s.

The income of the College from all sources during the past year amounted to £35,372 6s. 2d., derived principally, as already shown, from fees paid by candidates for the diplomas of the College—viz., £22,859 17s. Rents from chambers adjoining the College produced £2020 4s. 8d.; dividends on stock, £803 10s. 10d.; from members of the Council and Court of Examiners on their election, £84; election to Fellowship, £10 10s.; sale of stock, £8617 10s.; from trust funds, sale of Calendar and Synopsis, &c., £976 13s. 8d.

The expenditure for the year amounted to £33,742 14s. 7d. (leaving a balance at the bankers of £1742 14s. 7d.), the largest item being for the Savoy Estate, £11,852 11s. 9d.; the next largest amount appears in fees paid to examiners, £9685 15s. Salaries, wages, and pensions for officers and servants of the College in the three departments, library, museum, and office, amounted to £4585 8s. 4d.; taxes, rates, diploma stamps, and insurance absorb the sum of £1901 12s. 5d.; half expenses for Examination Hall, £651 2s. 8d.; under miscellaneous items, extraordinary expenses, alterations, repairs, fuel and light, printing and stationery, about £4000 appears to have been expended.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5312 births and 3151 deaths were registered during the week ending October 15th. The annual rate of mortality in these towns, which had been 17·5 per 1000 in each of the preceding two weeks, rose last week to 17·8. During the thirteen weeks of last quarter the death-rate in these towns averaged 20·4 per 1000, and was 0·5 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 14·2 in Leicester, 14·4 in Oldham, 14·7 in Leeds, and 15·0 in Brighton and in Derby. The rates in the other towns ranged upwards to 23·2 in Bolton, 24·0 in Preston, 24·5 in Manchester, 26·8 in Blackburn, and 27·1 in Plymouth. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 460 and 412 in the preceding two weeks, further declined last week to 382; they included 124 from scarlet fever, 68 from diarrhœa, 50 from measles, 53 from "fever" (principally enteric), 50 from whooping-cough, 29 from diphtheria, and 8 from small-pox. These zymotic diseases caused the lowest death-rates last week in Huddersfield, Plymouth, and Newcastle-upon-Tyne; and the highest rates in Preston, Blackburn, and Bolton. The greatest mortality from scarlet fever occurred in Birkenhead, Manchester, Bristol, Bolton, Preston, Halifax, and Blackburn; from "fever" in Oldham, Nottingham, and Preston; from measles in Derby and Bolton; and from whooping-cough in Halifax. The 29 deaths from diphtheria in the twenty-eight towns included 22 in London and 2 in Wolverhampton. Small-pox caused 8 deaths in Sheffield, but not one in Greater London or in any of the twenty-six other large towns. Only 5 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; whereas the number of cases of scarlet fever in the Metropolitan Asylums Board hospitals and in the London Fever Hospital had increased to 2159. The deaths referred to diseases of the respiratory organs in London, which had ranged in the preceding four weeks from 142 to 219, further rose last week to 280, but were 9 below the corrected average. The causes of 72, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Portsmouth, Brighton, and in eight other smaller towns. The largest proportions of uncertified deaths were recorded in Newcastle-upon-Tyne, Blackburn, Sunderland, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·7 and 18·1 per 1000 in the preceding two weeks, further rose to 19·8 in the week ending October 15th; this rate exceeded by 1·5 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 13·7 and 16·1 in Aberdeen and Edinburgh, to 22·4 in Glasgow and 24·3 in Perth. The 483 deaths in the eight towns last week showed a further increase of 30 upon the numbers returned in recent weeks, and included 80 which were referred to whooping-cough, 23 to scarlet fever, 14 to diarrhœa, 7 to diphtheria, 5 to "fever" (typhus, enteric, or simple), and not one either to small-pox or measles; in all, 79 deaths resulted from these principal zymotic diseases, against 71 and 74 in the preceding two weeks. These 79 deaths were equal to an annual rate of 3·2 per 1000, which exceeded by 1·0 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 28 and 17 in the previous two weeks, rose last week to 80, of which 10 occurred in Glasgow, 7 in Greenock, 5 in Edinburgh, 3 in Dundee, and 2 in Leith. The deaths from scarlet fever, which had been 11, 12, and 19 in the preceding three weeks, further rose last week to 23, and included 8 in Glasgow, 7 in Dundee, and 3 in Perth. The 14 deaths attributed to diarrhœa, of which 5 occurred in Glasgow and 4 in Leith, showed a further decline from recent weekly numbers. The 7 deaths from diphtheria corresponded with the number in the previous week, and included 5 in Glasgow. The 5 deaths referred to "fever," of which 3 were recorded in Paisley and 2 in Edinburgh, showed a further decline from the numbers returned in the preceding two weeks. The deaths attributed to acute diseases of the respiratory organs in the eight towns, which had been 83 and 78 in the preceding two weeks, rose again last week to 83, but were 15 below the number returned in the corresponding week of last year. The causes of 54, or more than 11 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 30·9 and 24·2 per 1000 in the preceding two weeks, rose again to 27·3 in the week ending October 15th. During the thirteen weeks of last quarter the death-rate in the city averaged 31·0 per 1000, the mean rate during the same period being but 19·6 in London and 18·2 in Edinburgh. The 185 deaths in Dublin last week showed an increase of 21 upon the number in the previous week; they included 11 which were referred to scarlet fever, 9 to diarrhœa, 7 to "fever" (typhus, enteric, or simple), 6 to measles, 2 to whooping-cough, 1 to diphtheria, and not one to small-pox. Thus the deaths resulting from these principal zymotic diseases, which had declined in the preceding eight weeks from 78 to 29, rose again last week to 36; they were equal to an annual rate of 5·3 per 1000, the rate from the same diseases being but 2·0 in London and in Edinburgh. The 9 deaths attributed to diarrhœa showed a further decline from recent weekly numbers. The 11 fatal cases of scarlet fever, however, showed an increase, and exceeded the number returned in any previous week of this year; the deaths referred to "fever" also showed an increase upon recent weekly numbers. The fatal cases of measles, whooping-cough, and diphtheria corresponded with the numbers in the previous week. The deaths of infants showed a decline, while those of elderly persons were more numerous. Seven deaths from violence, but only two inquest cases, were registered; and 43, or nearly a quarter, of the deaths occurred in public institutions. The causes of 23, or more than 12 per cent., of the deaths registered during the week were not certified.

AT a meeting of the members of the Redcar and Saltburn Local Boards, on the 14th inst., it was decided that it was advisable to provide hospital accommodation for cases of infectious disease occurring in the said districts, and a committee was appointed to find a suitable building or site for a building.

"Audi alteram partem."

THE RECENT HONOURS EXAMINATIONS AT THE UNIVERSITY OF LONDON.

To the Editors of THE LANCET.

SIRS,—You were good enough some months ago to allow me to draw attention in THE LANCET to the new regulations introduced in 1887 with respect to the Honours Examination at the Intermediate Bachelor of Medicine Examination of this University. With your permission, I would now draw attention to the results of the examination in July last, the first under the new regulations. The examinations for honours were in the four subjects of the pass examination—viz., in Anatomy, Physiology, Chemistry, and Materia Medica. The total number of places obtained in the honours list was 18 only, obtained by 13 individuals.

	1st class.	2nd class.	3rd class.
Anatomy	1	1	1
Physiology	2	2	3
Chemistry	1	1	0
Materia Medica	0	4	2
Totals	4	8	6

The places were distributed among the various schools as follows:—University College obtained 7 places; St. Thomas's, 4; St. Bartholomew's, 3; Owens College, 2; London Hospital, 1; Edinburgh University, 1. The other schools do not, I fancy, appear on the list. If we neglect the numbers of those who passed in the second division, as well as those who omitted one of the subjects of examination, we find in the first division 22 names, distributed among the schools as follows:—Guy's, 6; St. Bartholomew's, 4; London, 2·5; St. Thomas's, 2; London School of Medicine for Women, 2; St. George's, 1; St. Mary's, 1; Newcastle, 1; Queen's and Mason's Colleges, 1; University College, 0·5. The disproportion between these numbers and those in the honours list is marked. It is unlikely that those whose names are in the first division were all of them inferior in point of attainments to those who obtained honours. It is much more likely that the majority were afraid to risk being plucked for the chance of getting into the more honourable list. Although naturally wishing that my pupils should obtain honours, I have refrained from urging them to compete under the present conditions, knowing that the medical student, as a rule, cannot afford to be delayed a year by a rejection at his Intermediate Bachelor of Medicine or any other examination which is not absolutely avoidable. I cannot help fancying that others have been similarly influenced.

In bringing this letter to a close, I may add that my dislike to the new regulation is shared by all the teachers (with one exception) with whom I have been in communication on the subject since I wrote to THE LANCET at the beginning of the year, and that they, as well as many students, have expressed hopes that the annoying restrictions will be abolished.—I am, Sirs, yours very truly,

VINCENT D. HARRIS, M.D. Lond., F.R.C.P.

Wimpole-street, W., Oct. 1887.

THE PROTECTION OF LEICESTER BY VACCINATION.

To the Editors of THE LANCET.

SIRS,—In your issue of last Saturday appears a letter from Mr. Bigge on the "Protection of Leicester by Vaccination," in which some reference is made to me. I have neither the wish nor the intention of entering upon a discussion through the press upon this subject, but I desire simply to correct certain misstatements and erroneous conclusions contained in the letter alluded to.

1. "That out of nearly a dozen persons who came in contact with the last case of small-pox here, two only submitted to revaccination." As far as my knowledge goes, the persons who came in contact with this patient after the eruption appeared and it was known to be small-pox were the medical officer to the Union Infirmary, the attendant on him there, myself, the porter at the small-pox hospital, and the two nurses who attended him there; one of these latter had had small-pox; the remaining five persons were all protected by revaccination. A man who had slept on the bed the patient occupied before going to the workhouse, and before the eruption showed itself, was also for safety revaccinated. The sanitary inspector who disinfected the room he occupied &c. was also protected by revaccination.

2. "That the health reports of Leicester prior to 1886 say nothing of the practice of revaccination." Inquiry from the late medical officer of health or from the inspectors would have supplied the information that this was done whenever the persons exposed to infection permitted, but this, like isolation in hospital, cannot be compulsorily enforced.

3. That my 1886 report "has given rise to all the misrepresentation" can be disproved by your Commissioner, whose article was, I imagine, based on much wider data than that.

4. That "the sanitary staff consists of one chief inspector, three sub ditto, one office clerk, and the officer of health. Of this number the chief inspector, one sub-inspector, and the clerk have not been vaccinated since infancy, and the protection must have ceased long ago." The last statement you have dealt with in your remarks. Respecting the staff, I would say the clerk never leaves the office, and has nothing to do with any case of infectious disease, and is an old man upwards of sixty years of age. The chief inspector has only been in office four years, and he himself comes scarcely at all in contact with any of our cases of infectious disease, this devolving upon the sub-inspector in whose district the case occurs. Moreover, he had good cicatrices of primary vaccination. The sub-inspector alluded to as not being revaccinated has been appointed scarcely two years, and has never yet had to do with a single case of small-pox. He has good vaccination marks, but it is more from oversight than anything else he has not yet been revaccinated, which he intends to have done promptly on the first occasion of having to deal with small-pox, but probably before waiting for that. The sub-inspector whom he succeeded, and who had often to deal with small-pox, was *vaccinated* and *revaccinated*. A most important member of the staff has been omitted from the above list altogether—i.e., the man who disinfects all the infected rooms, houses, &c.; he is vaccinated and re-vaccinated.

5. "That the nursing staff at the hospital consists of the matron and two nurses. Of these, the matron has not been vaccinated since infancy; one nurse nineteen years since revaccination; the other revaccinated unsuccessfully, and contracted small-pox immediately after. An experience unique and interesting." To that I would say that the nursing staff consists at present of a matron and six nurses, but at the time referred to I believe we had six or eight nurses. All who at the time had not been revaccinated or had small-pox were then revaccinated immediately on the admission of the case of small-pox. The matron has not been revaccinated since childhood, but she had good cicatrices. Further, when a case of small-pox is in hospital she can scarcely be said to come in contact with it, as the small-pox building and nurses in charge thereof are carefully isolated from the rest of the buildings and inmates. The "nurse revaccinated nineteen years ago" would be revaccinated since puberty was reached, rendering her tolerably safe for life. The reference to the unsuccessfully revaccinated nurse is rather unfortunate for Mr. Bigge's argument. There is nothing unique in a person not revaccinated contracting small-pox. In this case the nurse was on duty at the Oldham Fever Hospital, where no small-pox had been admitted for some time, and several fresh nurses engaged in the interval had not then been revaccinated. A case came in; Dr. Sutton at once revaccinated those who had not been thus protected, but, not being able at the moment to obtain recent lymph, used some that had been in his possession a considerable time, and apparently become inert, for this, both in nurse and a servant, failed "to take," and in a fortnight both were suffering from small-pox. Further, the porter who refused revaccination also contracted it.

6. "That of four nurses since appointed, two only have been revaccinated since childhood." If it is meant since the last case of small-pox was admitted four nurses have been appointed, this is wrong: at least a dozen nurses have come and gone since then; but, having had no small-pox here, the question of revaccination has not been considered by me.

7. "That at the last admission of a small-pox case the

nurse attending was not revaccinated, although an assistant was operated on." The nurse in charge was the one just referred to as having passed through an attack of small-pox at Oldham, and was therefore well protected, the assistant nurse was successfully revaccinated by me before going on duty.

8. "That we have therefore ten persons who were in office at the time the report was made, *four of whom had never been vaccinated*, one in whom the protection had vanished. Of the remaining five, the most recent revaccination was performed two years ago." In the absence of any particulars, by the ten persons here referred to, I take it, are intended myself, the chief inspector, three sub-inspectors, the clerk, the matron, the two nurses who attended the case, and the porter; of these *all had been vaccinated*, and *all who came in contact with the patients were revaccinated.* I am, Sirs, yours faithfully,

HENRY TOMKINS,
Leicester, Oct. 18th, 1887. Medical Officer of Health.

JAMBUL IN DIABETES; SACCHARINE IN DIABETES.

To the Editors of THE LANCET.

SIR,—Mr. Hurry Fenwick's letter induces me to give you the results of the trial I have made of jambul powder in five cases of diabetes since the date of Dr. Kingsbury's letter to one of your contemporaries, used in doses of five grains, generally four times, in two instances three times, daily. All the patients were in the General Hospital under my care. I may say at once that no case was cured, but that all left the hospital more or less relieved by treatment, that all were carefully dieted, and that, besides the routine of diet, they were allowed potash imperial, sweetened with glycerine, to drink, and were in several instances treated by vapour baths. The effects of jambul were tested by maintaining uniformity of conditions in all other respects during the time the drug was employed or its use omitted. There were eight distinct trials in the five cases, five being followed by an increase of sugar and three by a decrease. Its disuse was followed on four occasions by a decrease and twice by an increase.

H. G——, aged thirty-five, was the only case in which the decrease was well marked. On admission he passed 250 oz. of urine containing 9200 gr. of sugar. After being placed on a diet of meat, greens, and gluten bread, and the urine observed for a week, he passed an average of 190 oz. daily, containing 4500 gr. of sugar. He then took 5 gr. of jumbul three times a day for twenty-four days, during which time he passed on an average 140 oz. of urine containing 3500 gr. of sugar. The next week he took no medicine, and the urine fell to 104 oz., containing 2400 gr. of sugar. He was then given 1 gr. of opium twice daily for twelve days, the urine falling to 78 oz. and the sugar to 2000 gr. This patient is still under observation.

In this case there seemed to be an improvement taking place independently of the drug, and which in no way ceased when this was discontinued. The other two instances where its use was followed by a decrease were neutralised by the fact that subsequent trials in the same patients were followed by an increase. Thus, in W. S——, aged twenty-one, the first trial was followed by a decrease, the second by an increase; and in F. M——, aged thirty-one, the first and third trials were followed by an increase, the second by a decrease. The duration of the use of the drug varied from three to thirty-five days. The five trials that resulted in an increase were respectively three, five, thirty-five, twelve, and fifteen days, while the three resulting in a decrease were three, eight, and twenty-four days. As far as possible the conditions were identical, so that if the drug is to be credited in any instance with the reduction of sugar, it must also be debited with its increase in the other instances, and we must conclude that it did more harm than good to my cases. I do not, however, think so harshly of it; I believe it to be a very harmless substance, and incapable of action either for good or evil. It deserves just as little to be regarded as a specific for diabetes as does arsenite of bromine, salicylate of sodium, bromide of potassium, codeine, salicine, boracic acid, or uranium nitrate, each of which has found enthusiasts to believe in it. I discussed the claims of these drugs in a paper published in the *Practitioner* for December, 1886, to which I would refer any reader who desires to know more of my opinions as to the rational use of drugs in diabetes.

One word as to saccharine. A convenient solution for sweetening purposes may be made by using bicarbonate of soda as a solvent, in the proportion of five grains of bicarbonate of soda and ten grains of saccharine to one ounce of water; a teaspoonful is sufficient to sweeten a cup of coffee. In preparing potash imperial for diabetic patients, four grains of saccharine to the pint are sufficient to make it very distinctly sweet. Saccharine is not expensive; I understand it can be sold retail at about 1*s.* 6*d.* a drachm.

I am, Sirs, yours truly,
ROBERT SAUNDBY, M.D. Edin., F.R.C.P. Lond.
Birmingham, Oct. 10th, 1887.

"THE PRESYSTOLIC MURMUR, FALSELY SO CALLED."

To the Editors of THE LANCET.

SIRS,—I have read with considerable pleasure the attack on the auricular systolic murmur, as such, by so eminent a member of the profession as Dr. Dickinson, contained in the first part of his paper, "The Presystolic Murmur falsely so-called." He treats the subject from a physician's aspect; may I be permitted to make a few remarks from an anatomical standpoint?

In considering the causation of the murmur, a comparison is necessary between the normal and the stenosed mitral orifice, more especially with reference to the position of the valves during diastole and beginning contraction. During the diastole of the ventricle blood from the pulmonary veins is gradually filling the auricle, flowing on into the ventricle, lifting up the valves from the ventricular wall, and producing an orifice similar to, though larger than, the stenosed one. The auricular contraction commencing in the great veins forces the blood through this funnel-shaped orifice into the ventricle, the effect of which is the distension of the ventricle and the complete approximation of the valves before the commencement of the ventricular contraction, thus preventing any regurgitation. I am aware that this latter assertion is denied, and that many prefer to regard it as being brought about by the beginning ventricular contraction. In support of what I have stated I may mention the following experiment, well known to your readers:—

The heart being removed from the body, with the ascending part of the arch of the aorta and pulmonary artery, which are tied so as to occlude their orifices, the left auricle is opened, and a stream of water is made to flow through the mitral orifice; the valve segments are then seen to leave the ventricular wall, and gradually to approach each other; the stronger the stream, the more rapid and firm the approximation. Instead of water, I have often, with a like result, used air, by placing the nozzle of a syringe at the mitral orifice and forcing air into the ventricle—this under conditions similar to those existing in the body. If a force, therefore, equal to the auricular contraction can approximate the valves, why is it necessary to assume that these are only approximated by the commencing ventricular contraction?

In applying the above experiment to a heart with a stenosed mitral orifice, I have noticed that such is not closed until a greater force of water is used than is necessary to close a normal mitral orifice. And in stenosis, with a definite ventricular systolic murmur during life, the orifice cannot be accurately closed by such procedures. This being allowed, then, it follows that the auricular contraction will not approximate the thickened fibroid valve segments, or will not completely close the funnel-shaped aperture bounded by the ring of adherent valve segments present in mitral stenosis. The ventricular contraction following, regurgitation through the imperfectly closed mitral orifice results; it is this regurgitation which has been described as of direct mitral origin. Again, as Dr. Dickinson points out, may not the character of the murmur be an additional argument in favour of the ventricular systolic theory? For has it not been described "as running up to the systolic sound," and "increasing in intensity until lost in the systolic sound"? If the mitral valves at the beginning ventricular contraction are not approximated, but become so during its contraction, the orifice will therefore become narrower and, the force remaining the same or increasing, the resulting murmur will increase in intensity, and on the complete approximation of the valves will be followed by the sharp sound

Digitized by Google

which, though described as the first sound, yet differs materially from the booming character of the normal first sound. I am, Sirs, yours very sincerely,

Crewe, October 4th, 1887. W. OWEN TRAVIS.

To the Editors of THE LANCET.

SIRS,—By a somewhat remarkable coincidence two men of unquestionable ability and originality have almost simultaneously attacked the commonly accepted belief on the manner of production of the so-called presystolic or auriculo-systolic murmur—a murmur which, curiously enough, is accepted by observers as of all cardiac murmurs the only one the mere recognition of which is absolutely diagnostic of organic valvular disease. Dr. Dickinson in your own pages, and Dr. McVail before the Medico-Chirurgical Society of Glasgow (*Brit. Med. Jour.*, Oct. 8th, 1887), have both asserted their belief that the auricular contraction is incapable of producing the presystolic murmur, which, they say, is really ventricular systolic in its rhythm and regurgitant in its nature; and Dr. McVail has gone into elaborate detail to show its method of production. Now, it seems to me that, without discussing the position further—and there is much room for discussing it,—there is one series of well-ascertained facts which is absolutely fatal to its acceptance. The presystolic murmur as we general practitioners see it—and it is exceedingly common—occurs in the majority of cases in a heart which is perfectly regular in its action and moderate in its rate of contraction, and is thus in a condition favourable to its careful study. It begins *almost immediately* after a faint and perhaps reduplicated second sound, and runs right on to the short, sharp, and loud first sound (or what represents the first sound), and thus it abruptly ends. Occasionally this is followed by an ordinary ventricular systolic murmur; but its existence is of no importance to my present purpose. Then comes the second sound again, in its usual course, and the cycle is complete. Now, if the theory which these observers advance be correct, the ventricular systole commences *immediately* after the closure of the sigmoid valves, and ends only with their closure a second time; for it is clear that, whether there be a characteristic mitral systolic murmur present or not, the completion of the ventricular contraction must be at once followed by the closure of the sigmoid valves, and the production therefore of the second sound. In the extremely brief period, then, which intervenes between the completion of the ventricular contraction and the production of the second sound, *plus* the short period during which that sound lasts, *plus* the very brief interval which elapses before the murmur begins again, we are asked to suppose that there occur, in succession, the cardiac pause, the ventricular diastole, the auricular contraction, and the complete ventricular distension; whilst, on the other hand, the ventricular contraction, which we have hitherto regarded as short and sharp in its character, is drawled out, as it were, during the long presystolic murmur, the occurrence of this first sound, and up to the fraction of a moment before the occurrence of the second sound. In other words, we are asked to believe that all the essential work of cardiac rest, collection of blood in the auricles, and the filling of the ventricles, takes up greatly less than the half of a cardiac revolution, whilst the work of emptying the ventricles into the great arteries takes up far more than the half, and that, too, in the case of a left ventricle, which in uncomplicated cases is undilated and unhypertrophied, if, indeed, it be not actually atrophied. It seems to me, therefore, infinitely more difficult to accept the position which is being now proposed to us, than to believe that the contraction of the auricle is itself the cause of the murmur. How strangely views change on these matters, for not seventy years ago Laennic believed that the auricular contraction was sufficient to explain the second sound, and was, indeed, its cause. There can be little doubt that he not only recognised the presystolic murmur, but correctly connected it with contraction of the mitral orifice, rightly thinking it auriculo-systolic in rhythm, but unfortunately basing his opinion upon the false belief that the contraction of the auricle was the cause of the second sound. But why should it be thought so impossible for the auricular contraction to produce this long rough murmur? If there is a true diastolic mitral murmur, there can be no other possible explanation for it than that the current of blood, accelerated perhaps by the suction power of the dilating ventricles, is thrown into sonorous vibration as it passes over the thickened and roughened cusps of the mitral valve. And if this be so, why should the still more accelerated current of blood forced into the ventricle through a narrowed orifice by the prolonged contraction of a dilated and hypertrophied auricle be unable to produce an audible sound? Indeed, it is not to be forgotten that a murmur, prolonged and even musical in quality, can be produced under circumstances of surprisingly little force or rapidity of current, as is evidenced by the occurrence of the *bruit de diable* in the veins at the root of the neck.

I am, Sirs, yours truly,

Paisley, October, 1887. FRANK SHERAR, M.B. Glas.

"COMPULSORY NOTIFICATION OF INFECTIOUS DISEASE."

To the Editors of THE LANCET.

SIRS,—Dr. Jacob has misapprehended the purport of my letter in your issue of the 8th inst., in which I did not undertake to prove anything, but merely stated that compulsory notification of infectious disease was acceptable both to the profession and laity of Reading, and worked smoothly and well. The question of its value as against disease is a different and larger one, to which the demands upon my time will not permit me to do justice, nor can I, owing to the death of our medical officer of health, under whose supervision our present system has grown up, obtain access to, or deal with, the statistics of the borough, as he, had he been alive, would have done.

1. I much regret that I am unable to give a satisfactory reply to Dr. Jacob's first question as to the influence of compulsory notification on the death-rate from zymotic disease. The reason is that until November, 1875, Reading had no complete system of drainage, and during the past ten years the number of houses connected with that system has been gradually increasing from 2003 in 1876 to 8765 in 1886. Therefore the two factors of improving house sanitation and compulsory notification have been concurrent, rendering it impossible to ascertain to what extent each is responsible for the reduction of the zymotic death-rate from 2·88 per 1000 of the population in the five years 1876 to 1880 inclusive to 1·96 in the next quinquennial period 1881 to 1885, being a reduction in five years of nearly 1 per 1000 living.

2. The notification certificate is a plain statement that, in the opinion of the practitioner, A. B. is suffering from an infectious disease, and specifying the situation of the building, the name of the occupier, and the nature of the disease. The practitioners here feel that they and the medical officer of health have no conflicting interests, and the latter uses his own discretion as to whether he visits the house, sends his inspector, or does neither. Our late medical officer was on the best terms with all the medical men, and would, if he thought it necessary to visit a house, consider the wishes of the medical attendant, and go with or without him, as the latter might prefer. He never interfered unpleasantly, his assistance was constantly requested, and his visits objected to by none. The disinfection and sanitation of the house was, in the case of intelligent and well-to-do householders, left to the direction of their own doctor, who could obtain, if he liked, the services of the officers of the sanitary authority, or have the same carried out by other competent persons. In the case of the poor, disinfection was carried out by the authorities, and both doctors and patients were glad to have it done. In *all* cases, on the receipt of the certificate, a printed notice was sent enjoining isolation for a specified time from the date of the last case in the house, giving particulars as to the disease and its sanitary treatment; direction for proper disinfection of the patient, premises, and clothing; advising medical attendance, and reciting the penalty for the various infringements of the Act of Parliament by infectious persons. It cannot be denied that all this is useful and to the point in tending to make people careful, and so limiting the extension of disease; and without compulsory notification these precautions could not be advocated, and probably would not be adopted. Errors in diagnosis of course occur, and in cases felt to be doubtful it is quite usual for the practitioner to ask the medical officer of health to see the case and give his opinion as to its nature. I have asked dispensary and club doctors, and they assure me that the Reading working classes have no objection to notification, and no dread of

Digitized by Google

the assistance, miscalled interference, rendered them by the health officers.

3. I have inquired of the two registrars as to the number of deaths certified by chemists and other unqualified persons. One with an experience of over eighteen years tells me that in all that time he has had none in adults. The other in five years has had one adult death certified by a herbalist. The only exceptions given by both are those of babies, all under one week old and certified by midwives. These are very infrequent. In every case where the death is not certified by a qualified practitioner the registrars invariably communicate with the coroner, who uses his discretion as regards an inquest. I think these facts refute this objection, at least as applied to Reading.

But why should Dr. Jacob require a mathematical demonstration of lessened death-rate through compulsory notification? Attached to zymotic disease is a certain percentage of deaths. In compulsory notification we have a machinery by which the spread of these diseases may be reduced, and therefore, potentially, a certain number of deaths prevented. If preventive medicine be equally with curative a function of the practitioner, I do not think I require stronger ground for my advocacy. Some two or three years ago the late Dr. Shea observed that notifications of diphtheria were coming in from one particular district, and on inquiry found that all the children first attacked attended the same Board school. Inspection showed that the sanitary condition of the school was defective, and the school was immediately closed until the defects were remedied and the outbreak was at an end. This is one out of many instances in which we have been indebted to compulsory notification.

The following extracts from the last report, dated January 1887, by our late medical officer of health, still further illustrate the advantages of this institution:—"No outbreak of epidemic disease has arisen during the year requiring the compulsory closure of any elementary school, but the usual precautions of recording the names of the schools attended is continued, and children from infected houses are prevented from attending Sunday and day schools, or other gatherings. The compulsory notification clause is much needed in the suburbs, where cases often arise that are not notified." "In several instances, upon my advice, the work of needlewomen, laundresses, and other persons was stopped where scarlet fever existed in their houses, compensation to a moderate extent being paid them for the time; and the power to do this was very useful, and to a great extent prevented hardship, for the relieving officer could afford no aid beyond offering 'the house' to the entire family, which would have broken up their home." "Small-pox was very prevalent in the county of Berks, and in adjacent districts last year several troublesome outbreaks occurred. The infection was brought into the borough on four occasions; but the cases being at once removed, and the ordinary precautions adopted on the premises from whence they came, there was no extension of the disease. This was the more fortunate, as the cases arose in very small houses and in two small beer-houses of a very similar class to a common lodging-house." Again, having in view the still further perfecting of his preventive measures he writes: "Scarlet fever was rather prevalent. A mild type existed, and though 236 cases were reported only eight proved fatal. A few were isolated in the cottage. Notification of cases of scarlet fever without the means for isolating them is very much reduced in value. Children from infected houses can be prevented from attending school, certain trades can be controlled, and where scarlet fever prevails the taking in of needlework and washing can be prevented, but the chief means for arresting the disease is wanting if the first cases cannot be removed to a hospital." Dr. Shea hoped that in time he might be able to establish a small hospital for infectious isolation. Lastly: "Notification of disease has proved very useful in several instances during the past year. Since notification has been in force it has worked very smoothly, and without any friction or difficulty. This, I think, greatly arises from the fact that we have in Reading a body of gentlemen practising medicine who have always shown the most perfect willingness to assist in every way in their power in the prevention of the spread of infectious disease."

Such was the opinion of a most unprejudiced and very experienced sanitarian on the value of compulsory notification. In support of my plea for its national adoption I cannot do better than allude to an address on the National Value of Public Health, delivered by Sir James Paget, and published in the journals in June, 1884. In this, he says: "I take it for granted that a large portion of all national welfare is dependent on the work which the population can constantly be doing; or, if I may so express it, that the greater part of the national wealth is the income from the work which is the outcome from the national health." Then after dealing with statistics, he continues: "Thus we may believe that our whole population between fifteen and sixty-five years old do, in each year, 20,000,000 weeks' work less than they might do if it were not for sickness." After calculating this loss to the country in millions of pounds, he remarks: "The losses of work due to sickness among children must be very large. Consider the time which might be spent in good productive work if it were not spent in taking care of them while they are ill." He then refers to losses due to the deaths of those who die young, which he estimates at much more than £2,000,000 sterling per annum. After apologising for making money appear as a motive for doing things for which sufficient motives might be found in charity and sympathy, this eloquent and distinguished advocate, in answer to the question "What more is wanted?" replies: "A larger and more practical recognition of the value and happiness of good national health; a wider study and practice of all the methods of promoting it; or, at least, a more ready and liberal help to those who are striving to promote it."

On the grounds of philanthropy and of political economy, I venture to express the hope that the opponents of compulsory notification may at length recognise that in it we possess a method capable of beneficent results to the nation at large, and in no way inimical to the interests of the medical profession.

I am, Sirs, yours faithfully,

Reading, Oct. 17th, 1887. J. HOPKINS WALTHER.

THE PURGATIVE TREATMENT OF PERITONITIS.

To the Editors of THE LANCET.

SIRS,—I am quite disposed to attribute the success in Mr. Frank Sturges' case to the purgative pills, though I wish to point out that my advocacy of this treatment was confined to the peritonitis following surgical operations—a very different thing from the peritonitis of childbed. In Mr. Sturges' case the purgatives were given before vomiting was established, and they probably therefore got a chance of being effective. To be of any use the purgative treatment must be employed early, before distension has paralysed the intestines, and before incessant vomiting has made every effort to do anything by the stomach of no avail. In fact, I look upon the purgative method rather as a preventive of, or as a method of aborting, peritonitis, than as a way of curing it. This will be quite evident to anyone reading my paper on the subject. Yet very far advanced peritonitis may be cured by this method if the vomiting can be stopped, and this is best done by putting nothing, absolutely nothing, in the stomach for twenty-four or even forty-eight hours, and giving a fairly large dose of morphia by hypodermic injection. But puerperal peritonitis has as its base in very many cases a specific poison, against which purgatives and everything else are powerless. Even opening the abdomen and cleaning it out fails to obtain the large success in puerperal cases which it certainly has, in my hands at least, in suppurative peritonitis which is non-puerperal.

I am, Sirs, yours obediently,

Birmingham, Oct. 15th, 1887. LAWSON TAIT.

PROTECTION BY COMPLETE VACCINATION.

To the Editors of THE LANCET.

SIRS,—It may interest the public to know how completely two children were protected from small-pox by having been fully vaccinated.

I was called to a club patient suffering from small-pox, having taken the disease from his wife. Seeing that the wife, then just convalescent, was nursing a baby five months old who was perfectly well, and who had had but a pimple on its nose, which never proceeded to suppuration, I inquired if the child had been vaccinated, and examined the arms, which bore five large cicatrices each. Observing that I took notes of the case, the mother told me that a friend of her's, who took the disease after visiting her (living in the next house), also had a baby which she was

Digitized by Google

nursing, and which had entirely escaped the infection of small-pox. I visited this case, and found that the children had been vaccinated together a month previously at a public institution, by five scarifications in each arm. This child had perfect immunity from the disease; they were both of the same age.

Speaking of the result of vaccination in a family after the small-pox had been introduced into the home, on Sept. 24th, 1875, I was called to a private patient, an elderly gentleman, who had taken the small-pox when travelling in the country. After ordering complete isolation to an upper room in the house on the 26th, I vaccinated the wife, one of the daughters, and the servant; the other two daughters and a son had been vaccinated in the previous February. The wife, unassisted, nursed her husband (by desire). The vaccination in each case succeeded, and no member of the family took the disease.

The former case was fully developed, though not severe. The latter was a severe form of the disease. The wife was the husband's junior by, I should say, at least, twenty-five years.

I am, Sirs, yours truly,

Camden-road, N.W., Oct. 15th, 1887. EDWARD BATE, M.D.

THE SIXTH INTERNATIONAL CONGRESS OF HYGIENE.

(From our Special Correspondent.)

(Continued from page 735.)

Vienna, Oct. 11th.

As the resolutions adopted by the International Congress have not yet been published, it is impossible to form a clear and complete idea of what has been voted. There is, however, in a scattered form, ample evidence of the great amount of work and research that has been undertaken. For a thorough investigation of the opinions expressed and the votes accepted it will be advisable to wait until the publication by the committee of the full report of the Congress.

In respect to the work of the Sections, one of the most original papers read was that of M. Emile Trélat, on the Means of bringing the Heat of the Sun and Proper Light to Dwellings. This is a subject of such vast importance that it must be reserved for a special study. Meanwhile, it may be mentioned that M. Trélat insisted that every wall which did not receive the direct rays of the sun would rot and harbour the germs of disease. To secure this purifying action of the sun during winter, it was necessary that streets running from north to south should be twice as wide as the houses were high. For giving light within the rooms he conclusively proved that windows required to be heightened rather than widened. This led to a lengthy discussion, during the course of which Dr. Knauff of Berlin spoke of the caloric power a centimetre of space receives, and concluded by urging that Venetian blinds should be made to open in vertical instead of horizontal lines. Professor Baumeister urged that the direction of streets was of no importance, for what the house lost on one side it gained on the other. He further attacked the laws of Berlin for making no difference between the rules regulating the building of houses in the centre and in the suburbs of the town. Evidently it was possible to enforce in the suburbs much more severe regulations. Professor Cöhn of Berlin thought a debt of gratitude was due to France for having first introduced measures for the construction of windows in school rooms on scientific principles calculated to save the eyesight of the pupils. It was then proposed to thank M. Trélat for his report, and to proceed to the next subject. Baron de Sazor protested. He demanded that the Congress should establish principles, and should proclaim what was necessary in the first instance. It would be time enough to discuss whether these principles were practical or not when they had been firmly established. In St. Petersburg, which he had the honour of representing, all the new streets were fifteen metres wide, and it was not allowed to build a house higher than fifteen metres. The openings at the back of the houses were also fairly large, and there were rules to ensure sufficient light to the inhabited rooms. M. Trélat replied that rules for the construction of streets likewise existed in France, but they did not suffice to meet the case. The Russian regulations represented but a trivial progress, for the houses were one and a half times as high as the back yards were wide. With respect to the compliments Professor Cöhn had made to the French nation, they were really due to Professor Cöhn himself, for it was his work on Shortsightedness, written some fifteen years ago, which had induced the French Government to protect the eyesight of the children in schools. Baron de Sazor again rose to explain that he only gave details about the rules enforced at St. Petersburg in the hope that the Congress would pronounce a definite opinion that something better was required. In spite of this, the Section came to no decision. Some proposed to adopt M. Trélat's conclusions, others to merely thank him for his paper. In the confusion that resulted it was impossible to say whether either of these two proposals was adopted. No clear and decisive vote seems to have been taken. This was all the more unfortunate as M. de Sazor had evidently a definite object in view. Armed with a resolution from the Congress, he might have brought pressure to bear upon the authorities of St. Petersburg. It is to be regretted that the ability and special knowledge displayed in this discussion should not have brought about a definite conclusion.

The question of Teaching Hygiene in all Educational Establishments was very generally discussed, and the principle adopted. Many members of the Congress, however, did not seem to realise that the great difficulty, especially on the Continent, is to find competent teachers. Many speakers seemed to think that when they proposed to confine this task of teaching to medical men the whole difficulty was solved. But a great number, if not the majority, of medical men, on the Continent at least, have no knowledge of practical hygiene. As an English delegate inquired during the course of the debate, Was the Congress quite sure that even the doctors present knew how to test a soil pipe for leakage, how to direct the construction of drains, and detect the escape of sewer gas?

The debate in the Second Section on Factory Legislation was long and laboured. It was regrettable that Mr. F. H. Whymper, superintending inspector of factories, whose sketch of the working of the law in England formed, with a paper by Dr. Fridolin Schuler, of the Canton Glarus, Switzerland, the basis of discussion, was not present to take part in the votes on the resolutions. It was generally accepted that the local circumstances relating to factories differed so widely that no one general rule could be laid down relating to the amount of air, heat, and light required. In these cases special technical knowledge is necessary, and the method of factory inspection should be such as to admit in consultation those who possess the necessary practical experience. When serious dangers can only be prevented by the total suppression of certain industries—such as, for instance, the use of arsenic or phosphorus,—then such suppression should be the result of an international treaty, and should affect several nations simultaneously. A very excited discussion arose as to the Half-time System. It was generally felt that if the children were allowed to go to work before they had completed their education, this practice would become a means of making them work too early in life. On the other hand, it was objected that the half-time system had given the best results, and that many children would complete their education before the law allowed them to work; this would enable them to waste a year or two in lounging about the streets, to the great detriment of their health and morals. The conflict of opinion rendered it impossible to establish any definite rule on this question. The principle of State legislation for the limiting of the hours of labour, not only for women and children, but for men also, was approved on all sides, and a resolution in favour of an International Eight Hours Bill was almost carried. A ten hours' day was carried by a large majority, coupled with the desire that this should be regulated by an international treaty. The Saturday half-holiday was also approved. Then there was a resolution adopted to the effect that where, as in the piercing of tunnels &c., the employers had to provide food for the workmen, such food should be occasionally examined by independent inspectors. During the course of the discussion it was pointed out that three classes of inspectors were required: doctors for all matters relating to medicine and prophylaxis; specialists, whether doctors, architects, engineers, or others, for difficulties relating to drainage and ventilation of workshops and factories; finally, with respect to the various methods by which unscrupulous employers elude the law, to the detriment of the health of their

Digitized by Google

workmen, inspectors should be selected from among the victims themselves. A resolution to this effect was put late in the day, and when the room was nearly empty. It was defeated by 21 against 13; but in the majority there were no less than five manufacturers and several Austrian inspectors of factories. In Austria these inspectors are selected from among the commercial classes. The chairman himself was a factory inspector, and had been formerly employed by a chamber of commerce. Under these circumstances, while the working-class interests were not directly represented, members of the commercial and manufacturing classes, who are keenly interested in checking factory legislation, were present in large numbers, and took a very active part in the debates. This is scarcely fair. The object of the Congress should be to obtain the disinterested opinion of men of science engaged on sanitary reform, instead of having to listen for hours to manufacturers who are doing their utmost to prevent such legislative interference as will, while improving the health of the population, tend possibly to limit the present almost inexhaustible supply of cheap labour. In such matters it is difficult to prevent a collision between economical and sanitary problems; but, in any case, the points at issue should be debated purely on sanitary grounds, and the vote should not be influenced by persons who have their own financial interests at stake. In spite of this alien influence present in the Section, some very strong resolutions were carried by the doctors who assisted. One resolution, for instance, was proposed in favour of assimilating railway servants and private servants to ordinary workmen, with regard to such legislation as affected factories, the hours of labour, &c. This, at the first vote, resulted in a tie of 15 against 15; and at a second trial was carried by 15 to 9. The small number of voters in this Section shows how many members abandoned their work in consequence of the great difficulty of understanding what was going forward, as was mentioned in a previous letter.

In the same Section, Professor Erismann, of St. Petersburg, related how he had examined 100,000 workmen, and found that, on an average, those engaged in textile industries were not as tall as the other classes of workers. Their chest measurement and bodily weight were also inferior. These symptoms of degeneration of the textile workers were more particularly distinct among the spinners. In every respect also they took a longer time to grow. Finally, the lifting power of the hand was not so great as that of workers in other trades.

A Fourth Section was created for the hearing of papers without discussion, and here Professor Reis lectured on Colour-blindness among Railway Servants. He dwelt at length on the mode of examining the sight, and said that in all countries committees of physicians should meet to determine what methods were best, and to see, from time to time, whether these could not be revised. Professor Tessier of Lyons followed with a paper on Diphtheria, in which he expressed a belief that the virus was contained in dust, and that there was an intimate connexion between diphtheria in poultry and among human beings. In the same Section an essay by Dr. G. Treille, professor at French naval schools, on the Acclimatising of Europeans in Tropical Countries, was so warmly approved that the Section decided to reprint and distribute the paper at the cost of the Congress.

The discussion on the Trade in Rags, commenced at the Hague Congress, was resumed in the Third Section. Professor Corfield had prepared a report on this subject. He stated that the questions he had addressed to various interested parties resulted in very unsatisfactory replies. The trade would be thoroughly opposed to the projected packing of rags in a covering soaked in a corrosive sublimate solution. Dr. E. Vallin of Paris and Dr. Finkelnburg of Bonn spoke next. The latter drew a line between dirty linen and rags. He gave details of different cases of epidemics traced to importation of rags, and thought that they more frequently caused outbreaks of small-pox. The proposal to disinfect all rags by heat would cause too great an expense. Dr. Henri Martin, of Paris then read a masterly description of the scientific experiments made in the disinfection of rags. The difficulty had always been to reach the centre of a bale. He remarked that by dividing the bales it was possible to satisfactorily disinfect them at a cost of about £2 for a hundred bales or twenty tons. A long discussion ensued, in which it was suggested that no particular form of disinfection should be approved, as new inventions modified

The Third Section, in which the questions relating to Cholera had been discussed, was so overwhelmed with work that it had to form a sub-section, and here M. Chamberlain, as the representative of M. Pasteur, spoke on the results obtained by Preventive Inoculations against Anthrax. He produced numerous statistical tables. Two German physicians, Drs. Gaffky and Loeffler, formerly Dr. Koch's assistants, challenged these statements; but Dr. Lydtin of Karlsruhe said that good results had been obtained in South Germany by inoculations for the prevention of anthrax. With respect to swine plague, the upshot of the experiments made was not so satisfactory, and scarcely justified the confident recommendation of the process of inoculation. A very animated discussion ensued, and most of the speakers expressed their conviction that the scientific value of the Pasteurian methods could not be doubted, but that for practical application further experiments were necessary.

On the Saturday the Sections were to have terminated their work in the forenoon, but the Third Section met again in the afternoon, and a large crowd of members were present to hear M. Chamberlain on the Prevention of Rabies. He apologised for M. Pasteur's unavoidable absence, due to his indifferent health, and then delivered a most interesting lecture, which, unfortunately, the limits of space render it impossible to reproduce. He remarked that when M. Pasteur commenced his studies nothing was known of rabies. The virus was generally supposed to be in the saliva, but it was ultimately found that certain results could only be obtained by going to the nervous centres. Even then, when the nervous substance was merely injected under the skin, several weeks passed before rabies entered. Then M. Pasteur had the idea of introducing into the brain, by trepanning, the marrow of an animal killed by hydrophobia. By this means the results obtained were absolutely reliable. Illness commenced in fifteen days, and death took place on the twentieth day. Several hundred experiments have proved this. There is never a variation of more than one or two days. In the presence of this double result, the possession of a true virus and a trustworthy effect, it seemed as if a basis of action had been found. M. Pasteur had all along conceived the hope of making a vaccine. Unfortunately, for rabies the same process could not be employed. M. Chamberlain then explained the various phases of research which led to the discovery of a method which could be relied on for attenuating this virus; how a young Alsatian volunteered to submit himself to inoculation, and how, with the success of this experiment, hundreds had come to be treated in a similar manner. It was impossible to say how many lives had been saved. There were no data on which to establish such a calculation. Some authors had maintained that the proportion of deaths from bites of mad dogs amounted to 36 per cent. The very least to be found in books on the subject was 16 per cent., and no one had ever pretended that the mortality was less than 5 per cent.; yet after vaccination the death-rate among M. Pasteur's patients had only amounted to 1·3 per cent. It could not be said how great the reduction in mortality had been, but it was impossible to deny that it was very considerable.

In the discussion that followed, one or two speakers related how they had failed in various experiments to bring about the expected and desired results. Others, on the contrary, expressed their entire satisfaction, and gave figures showing the number of persons who had been successfully treated. Dr. Metschnikoff of Odessa, notably, recognised the great work achieved by M. Pasteur, and proposed the compulsory vaccination of all dogs. M. Chamberlain had no difficulty in replying. He congratulated himself on finding that all parties approved of the principle of inoculation. The proposition to vaccinate all dogs was a proof that the principle was accepted. Some had spoken of negative results. The vaccine might easily be spoilt and other microbes gain admission. Material errors would, of course, produce negative results, and a certain amount of practical experience was necessary. In Paris there had been no failure whatsoever, and abroad many successes. M. Chamberlain explained where and how many errors in experiments had been made which falsified the result; and then concluded, amid the loud applause of a crowded room.

This brought the business of the Congress to a close; but on the following Sunday morning a formal meeting was held in the great hall of the University, when two papers were read: one by Dr. Conradi of Pavia, on the Connexion between Longevity, Anthropology, and Hygiene; the other by Dr. C. T. d'Inama-Sternegg, Royal and Imperial Councillor,

Digitized by Google

President of the Austrian Statistical Commission, on the most Remarkable Modifications which the European Populations have undergone during the last thousand years. When the papers had been read, the Congress decided to meet again in London in 1891, and elected a committee, as already mentioned, to organise the next Congress. A few short speeches then ensued. Dr. Mosso recalled the Congresses on the plains of Olympia, when Greece had reached the zenith of its civilisation. It was no longer the little States of Greece that met, but all Europe. The Congress would constitute a page in the history, not of tyrants and men of selfish ambition, but of humanity. In the name of Italy he offered his best thanks to the organisers of the Congress. M. Emile Trélat, in the name of France, spoke in the same strain. Hygiene progressed rapidly; the number of members of this Congress, amounting to 2500, proved the growing popularity of the new science. This result was due to good organisation and to the facilities which the vast building of the University afforded; but the amiability of the Viennese people had, more than all, facilitated the great work. "This soft amenity, which is true strength, had made the success of the Congress."

The name of the General Secretary, Professor von Grüber, was often associated with these speeches of congratulation, and certainly it is impossible to speak too highly of the devotion, the unfailing zeal, and the energy of the General Secretary. Thus the Congress came to an end. It was nearly two in the afternoon when the final cheers were given, and the members hurried away to prepare for the excursion to Buda-Pesth, and the farewell banquet given on the same evening.

In this comparatively brief account of the debates there are many important omissions. Numerous speeches and papers were read and delivered quite as interesting as those to which some allusion has been made. To their authors sincere apology is due, but the laws of measurement and of space are inexorable, and some sacrifices had to be made. It would not, however, be right to leave undescribed the marvellous reception, which lasted three whole days, accorded to the six hundred members of the Congress who went to Buda-Pesth. This most impressive and last phase of the Sixth International Congress will be the subject of a subsequent letter. In the meanwhile, it only remains to add that, under the gallery of the vast courtyard of the University, there was during the Congress a small sanitary exhibition. Here might be seen specimens of school furniture, of warming apparatus, a great collection of statistical charts, and the familiar exhibits of the English Ladies' Sanitary Association and the English Society for the Prevention of Blindness, with Dr. Roth in person to explain to all continental hygienists how the knowledge of sanitary questions was popularised in England. There were also ambulances, cooking stoves, portable hospitals, and many other kindred subjects. In every sense, therefore, the Sixth International Congress must have greatly contributed to spread the knowledge of sanitary questions in Austria and throughout Europe.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE.

At the Exhibition Theatre here on Saturday evening last, Dr. Meare gave a lecture on "First Aid in Cases of Accident." The lecture was ably delivered and well illustrated. Mr. Waynman Dixon of Sunderland, who presided, pointed out that, although a clause in the new Mines Act renders it compulsory for coal mines to keep on the premises the appliances necessary for giving first help to the injured, yet it is obvious that unless there be at the collieries persons who understand the use of such surgical accessories the provision made by the Act is absolutely valueless. Our ingenious *confrère*, Dr. Wm. Murray, has also been lecturing here on "The Evil Effects of Regular Habits," contending with much point and force that persons suffer in health from the monotony of over-regularity, and that a change is often indicated in the lives of these very regular people when they fall into bad health. Dr. Murray's lecture has given rise to a very brisk newspaper correspondence, but the lecturer's views seem to hold the field. There has been a considerable increase in fever cases in Newcastle; the last fortnight 126 cases have been notified, of which 93 were scarlet fever and 20 enteric. The Tyne Port Sanitary Authority during the last two months had inspected 1192 British steamers, 401 sailing vessels, 242 foreign steamers, and 197 sailing vessels, making a total of 2032. In all, 35 cases of sickness were found on board, and were inquired into and provided for; but two infectious cases were found, which were removed in the launch to the hospital. Only one vessel arrived which had been infected with cholera, and she was fumigated before entering the Tyne. The medical students who were under censure since the opening of the College have tendered an apology to the authorities, which has been accepted, so that they are allowed to pursue their studies this session. I am glad to hear that Dr. Luke Armstrong, whose late illness has been much exaggerated, is likely to very soon resume his professional work.

JARROW.

An unfortunate termination has taken place to a wedding feast at Jarrow, several people—about sixteen in all—having suffered from poisoning after partaking of a cake. So far there has been no death, but dangerous illness has resulted in many cases. The maker of the cake states that the only ingredients she used to "ice" the cake were half a pound of fine white sugar and the white of two eggs. She states that when she made the ice a fortnight ago she ate what was scraped off the edge of the dish, and also a little that dropped off the cake, when she was seized with similar illness to the Jarrow patients. The cake has been sent to the county analyst.

CARLISLE.

The inhabitants of the village of Burnriggs, about six miles east of Carlisle, are suffering terribly from typhoid fever. Thirty-seven cases of the disease have occurred, and four of them have already proved fatal. The sanitary authorities have traced the origin of the disease to a polluted well, which has now been closed. The village consists of about forty cottages, inhabited by between 120 and 130 persons, who for the most part gain a livelihood by working at the paper and woollen works in the neighbourhood. The local papers say that about one-third of the population has been stricken with fever.

(From our own Correspondent.)

OPENING OF THE WINTER SESSION.

On Tuesday, the 18th inst., the winter session at the University was inaugurated by an address to the students by Principal Sir William Muir, K.C.S.I. On behalf of the Senatus Academicus, which was largely represented on the platform, the Principal extended a welcome to the new comers on their entry into university life; while to the seniors he addressed an earnest appeal to make full use of the passing period of their student life that they might be well equipped for the work that lay before them in the active world in which they must play their part. Sir William then proceeded to review the developments which have occurred in the Scottish University system, and particularly in the University of Edinburgh, during the last fifty years. The growth which has occurred has not been a mere increase of size and numerical strength, but has been fraught with a gradual unfolding of the system of education, which has expanded widely as a whole, and has attained a much higher complexity in each of its parts. In surveying and depicting the main features of the student life of Scottish Universities, the speaker took occasion to compare it with other great centres of learning, and particularly with some of the newly-founded colonial universities. The main distinctive feature was the greater amount of personal independence that obtains here. This within duly guarded limits was a great advantage on the whole; but it had its drawbacks, among which was the fact that it did not imbue undergraduates with that feeling of corporate existence which tended to foster public spirit among them. Several attempts, and so far successful attempts, are now being made in Edinburgh to obviate this want; and these efforts had the Principal's warm sympathy and personal encouragement; in them probably lay the germ of a larger

Digitized by Google

system of colleges and halls of residence affiliated to, and under the control of, the University. Although large sums of money were frequently devoted by generous donors to kindred educational purposes, and fine public schools and colleges, such as Fettes' College, were established, it was unfortunate that no endowments had as yet been forthcoming for supplying students with so obvious a requirement as suitable residential establishments under efficient superintendence. When such funds were available he thought we might look for further improvements in our university system.

THE CONJOINT SCHEMES OF THE COLLEGE OF SURGEONS.

THERE will very soon be two Conjoint Schemes in connexion with the Royal College of Surgeons, one with the College of Physicians, and the second with the Apothecaries' Hall. On analysing the regulations of these two schemes, there appears but little material difference as regards the lectures &c. to be attended and the fees to be paid—viz., an additional course of lectures in anatomy, and of seven guineas in the examination fees. The Apothecaries' Conjoint Scheme, however, as it is less expensive, will no doubt prove a formidable opponent to the scheme of the College of Physicians; and, indeed, I should not be surprised, from what I hear, to find very soon that that corporation will withdraw altogether from any combination with the College of Surgeons. The exact date for the first examination under the Apothecaries' Conjoint Scheme has not yet been announced; probably it will be some time in November. Last week candidates were examined for the First Professional Examination of the Colleges of Physicians and Surgeons' Conjoint Scheme. Nearly one-half of the candidates were stopped on the papers, and two-thirds of the rejected failed in Physics alone, or combined with other subjects.

SANITARY CONDITION OF CORK.

Dr. Donovan, medical superintendent officer of health for Cork, in a recent report, states that the number of deaths from diarrhœa for the month and the previous month is unusually high, and the number of cases of typhoid fever is on the increase. This clearly indicates a weak spot in the sanitary condition of the city, which he believes is the general absence of cleanliness. No effort, it appears, has yet been made to carry out some of the suggestions made last year; among others the ventilation of the main sewers for which a sum of £700 was voted. He regrets also to state that the question of the domestic scavenging of the city did not meet with the consideration it observed, and he is of opinion that the city will never be kept clean until its scavenging is taken up by the Corporation, and until Cork is kept clean diseases such as diarrhœa and typhoid fever will prevail.

ALLEGED CURE FOR HYDROPHOBIA.

The treatment adopted by Mr. McGovern, of Legnagrow, co. Cavan, has impressed a large number of observers, and in consequence it is intended to form a committee to examine and report upon the subject.

At a meeting of the Fellows of the College of Physicians this week, Drs. Gordon, Grimshaw, and J. W. Moore were elected representatives of the College on the Committee of Management under the Conjoint Examination Scheme.

Dr. Aquilla Smith has again been re-elected representative of the College of Physicians on the General Medical Council.

(From our own Correspondent.)

THE CONSUMPTION HOSPITAL.

ABOUT two years ago Mr. Forster Green, a wealthy member of the Society of Friends in Belfast, offered to build a special wing for consumptives at the Throne Convalescent Hospital, on condition that the public would raise within one year a sum of £15,000 as an endowment, so that the new building, which would accommodate thirty patients, might not be a burden on the supporters of the hospital. Mr. Green most generously offered to extend the time for the raising of the endowment until the end of this year, and he also promised to contribute himself £1500. The total sum already subscribed or offered is a little over £7000, and a special meeting of the committee and life governors of the Royal Hospital was held last week to see what means could be devised to raise the additional sum. At this meeting it was finally decided to ask Mr. Blackiston-Houston, the Vice-Lieutenant of county Down, to give the Board of Management his assistance. I understand this gentleman attended the weekly meeting of the committee on Saturday, but regretted he was unable to give any help in the matter. To many it would seem, considering the present depressed condition of trade and the great depreciation in the value of landed property in Ireland, that it is well nigh impossible to raise such a large sum as £8000, but I trust that many of the wealthy citizens of Belfast will subscribe, so that Mr. Green's offer will be fulfilled, and a means afforded of relieving some of those afflicted with a disease which is extremely prevalent in Belfast.

HANS FLEMING, M.D.

Dr. Hans Fleming died at his residence in Omagh, co. Tyrone, on Friday, October 7th, in his seventy-fourth year. Dr. Fleming was the second son of John Fleming, Esq., of Ashfield, co. Meath, where his ancestors, who came from Holland, originally settled. Dr. Fleming, who was a Licentiate of the Irish College of Surgeons and an M.D. of St. Andrews, practised first in Balieborough, co. Cavan, and afterwards at Carrickmacross, co. Monaghan; and in both places he was much respected and had considerable success. He was appointed medical officer of the workhouse in Omagh in January, 1857, and held the office until 1885, when he resigned, and was succeeded by his son, Dr. Hans B. Fleming, who is now in active practice in Omagh. During the long period of his life spent in Omagh Dr. Fleming was universally respected. He was most attentive alike to poor and rich, and the immense concourse of the townspeople of Omagh and of the gentry of the surrounding districts at his funeral was a high tribute to Dr. Fleming's great worth.

Belfast, Oct. 19th.

PARIS.

(From our Paris Correspondent.)

ESSENCE OF TANACETUM VULGARIS.

IN the month of March, 1872, M. Peyraud, in his biological researches on the series of essences having isomeric relations, discovered an essence till then undescribed, which resembled in odour that of absinthe (wormwood). It was extracted from a synanthereus, the "Tanacetum vulgaris," which is still known under the names of "worm-herb," "horse-wormwood." This essence had till then been but little studied chemically and biologically. M. Peyraud remarked in his note to the Academy of Sciences at a recent meeting that, after injecting two drops of this essence in the veins of a rabbit, the animal was seized in about twenty seconds with terrible convulsions. It sprang forwards or backwards by bounds, and even upwards, generally falling on its left side. The teeth chattered, the animal bit its tongue, and there was an abundant flow of saliva from its mouth. The sense of hearing was greatly exaggerated. Moreover, when one held a stick near to the mouth of the rabbit, it bit it with such force that the animal could be raised without its letting go the stick. The convulsions lasted, on an average, from fifty to sixty minutes. The limit of the toxic dose scarcely exceeds three or four drops. To the convulsive period succeeded a comatose period of from two to three hours, during which the animal seemed insensible to any species of excitation. Finally the normal state returned, and the next day the animal did not appear to have been at all affected by the violent attack of the day before. After having remarked that the toxic effects of the essence of tanasia approached very little the epileptic type which is observed with that produced by the essence of wormwood, M. Peyraud assimilates them with the rabic type in the following terms: "All the phenomena of rabies are here

Digitized by Google

found—hallucinations, convulsions without loss of consciousness, opisthotonos, spasms of the muscles of the pharynx, of the larynx, and of the thorax, abundant salivation, asphyxic phenomena, sensorial excitability, tendency to bite, characteristic hoarse voice, diminution of the power of motion, momentary paralysis, sanguinolent froth from the trachea and the bronchi, subpleural hæmorrhage, sanguineous infarcts of the liver. We believe, then, that we are absolutely in the truth in giving to the tanacetic effects the name of *rage tanacétique, rage artificielle, simili-rage.*"

A PRECURSOR OF PASTEUR.

It would appear from the following note from the "Intermédiaire des Chercheurs et Curieux," cited from vol. i. of the "Traité des Erreurs et des Préjugés" of J. B. Salgues, Paris, 1810-11, that M. Pasteur has had a precursor in his theory of the cure of rabies by the inoculation of an attenuated virus of the same species: "The carnivorous animals, which are susceptible of contracting rabies, are also the only animals capable of communicating it. The innocent species, which live on fruit, herbs, and grain, might be able to receive but do not transmit it, as if nature wished by this happy exception to recompense them for their pacific virtues. This fact is now known to be constant, so that it would perhaps be possible to find in these animals a virus more mild, and to transmit it to the carnivorous species as they transmit the vaccine virus to the species susceptible of small-pox." Thus it may be seen that the above is enunciated as a simple hypothesis; but the idea is not the less singular.

THE ETIOLOGY OF TETANUS.

The etiology of tetanus divides pathologists into two camps. Those on one side admit that, if this malady frequently succeeds a wound, it may also originate without previous solution of continuity and under the influence of divers causes, the principal being cold; hence two forms—traumatic or surgical tetanus, and spontaneous or idiopathic or medical. For the others, the malady is always traumatic; whence two doctrines—that of *dualists*, and that of *unicists*. Professor Verneuil, who read a paper on this subject at the Academy of Sciences last week, entirely rejects the opinion of the dualists, and classes tetanus with microbian maladies, virulent or infectious. The pathological problem, he stated, then reduces itself to discover how and when the penetration of the virus is effected, and what circumstances favour or hinder it. "If, as the ancient unicists thought, penetration is always effected through a traumatic opening, the pathogeny, as simple as the etiology, would allow of only one process—breaking (*effraction*); but as the infection might take place when the solution of continuity of pathological origin, inflammatory or even traumatic, is covered over with a granular membrane, continued and protective, one may believe that the virus had penetrated without violence by a second mechanism, which would admit of a second form—tetanus by absorption. But as certain subjects appear to have no solution of continuity, recent or ancient, internal or external, but have been seized with tetanus by exposure to cold—by lying out, for instance, on a cold field,—nothing could prevent the idea that they had absorbed by the respiratory mucous membrane, or by the skin, supposed to be intact, the tetanic virus of which the soil is at times certainly impregnated; whence a second variety of penetration by absorption without any traumatic or pathological preparation, as occurs with malaria, and, without doubt, with scarlet fever, whooping-cough, &c." The dualism, therefore, the conception of which is combated by M. Verneuil, may be revived, but under another form, and in changing the terms of the problem, that is to say, one will not be able to tell whether the tetanus is medical, idiopathic, essential, traumatic, spontaneous, rheumatic, &c., which, however, is of no practical importance; but one would search with care where and by what process the virus had penetrated, and, if it be desired that their dichotomic division should be preserved, one may admit a tetanus by *effraction* and a tetanus by absorption. In any case, there will be no spontaneous tetanus, as a poison, always identical, playing the part of constant and necessary cause, will always be found.

Paris, Oct. 18th.

THE Duchess of Cumberland on the 15th inst. left the private asylum in which she had been confined since last March. Her Royal Highness is said to be perfectly cured.

THE SERVICES.

THE following arrangements have been made, subject to such modifications as may be deemed necessary, for the embarkation to England of the executive officers whose term of service in India will terminate during the trooping season of 1887-8.—By first troopship, Oct. 15th: Surgs.-Major W. T. Martin and G. Andrew, and Surg. R. R. Elmes. Second troopship, Oct. 29th: Surg.-Major T. M. O'Brien and Surg. E. J. E. Risk. Third troopship, Nov. 12th: Surg.-Major A. H. Ratigan and Surgs. J. W. Beatty and J. R. Yourdi. Fourth troopship, Nov. 25th: Brig.-Surg. R. P. Ferguson and Surg. G. H. Younge. Fifth troopship, Dec. 31st: Surgs.-Major Barker and J. Martin, and Surg. W. A. Morris. Sixth troopship, Jan. 14th: Surgs.-Major W. H. Clemo and O. F. Molloy, and Surg. G. T. Goggin. Seventh troopship, Jan. 29th: Surg.-Major J. P. H. Boileau and Surgs. W. Babtie and R. F. O'Brien. Eighth troopship, Feb. 18th: Surg.-Major J. Wilson and Surgs. J. McLaughlin and R. Fowler. Ninth troopship, March 17th: Surgs.-Major F. Dick and J. C. Dorman, and Surg. H. J. Peard. Tenth troopship, March 31st: Surg.-Major M. D. O'Connel and Surgs. F. P. Nichols and G. U. Brazier-Creagh.

ARMY MEDICAL SERVICE.—We are requested to state that no examination for commissions in the Medical Staff of the Army will be held in February, 1888. We presume this suspension of admissions into the Service is a result of the reduction of the staff consequent on the withdrawal of troops from Egypt.

Dr. Galbraith has been appointed Principal Medical Officer on the Staff at Suakim.

WAR OFFICE.—Army Medical Staff: Surgeon-Major Francis Patrick Staples to be Brigade Surgeon, vice St. John Killery, deceased (dated Sept. 20th, 1887). The undermentioned Surgeons to be Surgeons-Major (dated Sept. 30th, 1887):—John Findlay, M.B., Patrick Aloysius Hayes, William Mawer James.

ADMIRALTY.—The following appointments have been made:—Fleet Surgeon G. Bolster, to the *Excellent;* Surgeon J. Bagnall-Oakley, to the *Lizard;* Surgeon H. B. Beatty, to the *Bramble;* Surgeon A. Kidd, to the *Ready;* Surgeon J. Cashin, to the *Mistletoe;* Surgeon H. J. M'Todd, to the *Impregnable;* Surgeon W. C. Speller, to the *Ganges*, temporary; Surgeon W. R. N. Young, to the *Lily;* and Surgeon Horace K. Browne, to the *Royal Adelaide* (to date 18th inst.).

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Sherwood Foresters (Derbyshire Regiment): Surgeon C. A. Greaves, M.D., is granted the honorary rank of Surgeon-Major (dated Oct. 15th, 1887).—5th Lanarkshire (Glasgow, 2nd Northern): Acting Surgeon E. Kingscote, M.B., resigns his appointment (dated Oct. 15th, 1887).

Medical News.

ROYAL UNIVERSITY OF IRELAND.—The following have obtained the degree of Master in Surgery:

Robert Bryans, David C. Campbell, Robert J. Duffin, William M. Elliott, John Ellison, Robert J. Ferguson, Walter M. Hamilton, Gerald Hickey, William M. Killen, Hugh A. Logan, William M. Lewis, Richard C. Mc Cullagh, John Mc Elwee, Henry L. Mc Kisack, Samuel Matthews, Robert Nelson, D. J. O'Mahony, William J. O'Meara, Francis L. Sealy, John H. Sharpe, Cecil B. Shaw, John J. Shaw, Joseph Stewart, Henry J. Taylor, James Tomb.

The undernamed have passed the examination for the degree of Bachelor of Medicine:—

UPPER PASS DIVISION.—John Campbell, Robert Duffin, *W. M. Elliott, Gerald Hickey, *John J. Lynch, Richard McCullagh, *Henry MacKisack, *Robert Nelson, W. O'Meara, *Joseph Stewart.
* Eligible for the further examination for honours.

PASSED.—J. F. Annesley, Robert Bryans, James Clifford, H. R. Crofton, Francis B. Gahagan, G. R. Gordon, Walter M. Hamilton, W. M. Killen, J. McElwee, Peter McKenna, Samuel Mathews, Cecil B. Shaw, James Tomb.

The examiners have recommended that the following be adjudged to have passed the third examination in Medicine:—

James Gannon, Thomas Gorman, William Kirk, David McGee, Allan H. Mahood, Martin Molony.

COLLEGE OF PHYSICIANS IN IRELAND.—On St. Luke's Day (October 18th) the following office-bearers were elected for the ensuing year:—President: James Little. Vice-President: A. Foot. Censors: Drs. Foot, Nixon,

Digitized by Google

McSwiney, and Smyly. Additional Examiners: Drs. G. F. Duffey, J. B. Quinlan, and V. Macan. Examiners in Midwifery: Drs. Horne and Kirkpatrick. Additional Examiners under the Conjoint Examination Scheme:—Chemistry and Physics: Drs. Ashe and W. G. Smith. Materia Medica and Pharmacy: Drs. G. F. Duffey and J. B. Quinlan. Physiology: Dr. Purser. Medicine: Drs. Finny, Foot, Nixon, and Benson. Midwifery: Dr. W. J. Smyly. Hygiene and Forensic Medicine: Drs. McSwiney and Redmond.—Examiners for the Membership:—Practice of Medicine: Drs. McSwiney and Quinlan. Pathology: Drs. Purser and G. F. Duffey. Clinical Medicine: Drs. Nixon and Foot. Examiners for the Diploma in State Medicine:—Chemistry: Dr. W. G. Smith. Climatology, Meteorology, and Geographical Distributionary Disease: Dr. J. W. Moore. Vital Statistics: Dr. McSwiney. Hygiene: Dr. Nixon. Medical Jurisprudence and Pathological Anatomy in Relation thereto: Dr. G. F. Duffey. Professor of Medical Jurisprudence: Dr. Robert Travers.—Representative on the General Medical Council: Dr. A. Smith. Registrar: Dr. J. W. Moore. Treasurer: Dr. A. Smith.

IT is rumoured that typhoid fever has again made its appearance in the Royal Barracks at Dublin.

THE Town Council of Darwen have decided to erect a cottage hospital for that district.

IT is proposed to erect a hospital in the mining division of Redruth.

THE third anniversary of the inauguration of Hospital Sunday at Barnstaple was celebrated on the 16th inst.

On the 17th inst. the first stone of the Jubilee wing of the Northampton Infirmary was laid by Prince Albert Victor.

THE thirteenth annual meeting of the Sanitary Association of Scotland was held at Falkirk on the 14th inst., when several interesting and valuable communications were read.

THE first of a series of eight lectures under the Combe Trust was delivered on the 17th inst. in the Chemical Theatre of the Owens College by Professor Stirling. The subject of the course is the Physiology of Motion.

On the 19th inst., at an inquest held at the Marylebone Court as to the death of Mr. William Holland Baylis, a retired surgeon, evidence was given to the effect that it had been caused by morphia poisoning, and the jury returned a verdict of death from misadventure.

MEDICAL SUPERINTENDENTS' SOCIETY.—The inaugural meeting of the above Society will be held at the Paddington Infirmary, 285, Harrow-road, W., on Wednesday next, the 26th inst. At 3 P.M., Pathological specimens of Joint Disease, and cases of Rheumatism, Hysteria, Rickets, &c., will be shown, after which a paper will be read entitled "Lessons from Infirmary Work."

SPREAD OF LEPROSY.—According to M. Besnier, a member of the French Academy of Medicine, leprosy, far from disappearing by degrees, is spreading rapidly. Since the extension of the French colonial possessions, soldiers, sailors, traders, and missionaries have fallen victims to it in large numbers. M. Besnier, therefore, exhorts physicians in all countries to study the fell disease, in order to find a means of counteracting its ravages, for it has active foci of infection in every part of the globe. The malady is transmitted by a bacillus shaped like that found in tuberculosis. A discussion on M. Besnier's report will shortly take place in the Academy of Medicine.

COLONIAL AID TO UNIVERSITY COLLEGE HOSPITAL.—In response to the appeal from Mr. Berkeley Hill to old University College Hospital men resident abroad on behalf of the rebuilding fund of that institution, a meeting of former students was convened at the Oxford Hotel, Sydney, N.S.W., on June 14th, Dr. P. Sydney Jones in the chair. A subscription was started, the sum of £141 being promised by those in the room, and, according to advices recently received, the total has now reached over £200. Steps are being taken in the sister colonies to inaugurate similar funds, whilst from the interior of West Africa an answer in a tangible form has come to hand, showing that the *alumni*, though scattered, are not unmindful of the benefits conferred by their *alma mater*.

LADY DUFFERIN'S FUND.—The donations made in response to Lady Dufferin's special appeal in connexion with the Queen's Jubilee for further assistance to the National Association for Supplying Female Medical Aid to the Women of India, amount to £1700 received from England, and 478,000 rupees subscribed in India.

GLASGOW SOUTHERN MEDICAL SOCIETY.—The annual business meeting of the members of this Society was held on the evening of Thursday, the 13th inst., in their rooms, 11, Bridge-street, when the following office-bearers were appointed for the ensuing session, 1887-88:—President Edward McMillan, L.R.C.S.; vice-president, John Glaister, M.D.; treasurer, T. F. Gilmour, L.R.C.P.; secretary, James Erskine, M.A., M.B.; editorial secretary, R. A. D. Robb, M.B.; seal keeper, James Hamilton, M.B.; court medical, James Morton, M.D. (convener); James Dunlop, M.D.; J. Stuart Nairne, L.F.P.S.; David Tindal, M.D.; David N. Knox, M.A., M.B.; extra councillors, Drs. J. Brown, D. Couper, and J. Johnstone.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—Sir James Paget, Bart., President, took the chair at the quarterly court of directors held on Wednesday, October 12th. The death of one widow in receipt of £40 per annum was announced, and one orphan had ceased to be eligible for further grants. The death of one member was reported. Applications were read from sixty-three widows, five orphans, and three orphans on the Copeland Fund, and it was agreed that a sum of £1370 10*s.* should be distributed among them at the next court. The expenses of the quarter were £52 14*s.* Among the donations received since the last meeting of directors was one of £100 from "Alpha." It was decided that the centenary dinner should be held next year on October 29th, the anniversary of the first meeting of the Society.

TYPHOID FEVER AT CLUNY.—The educational establishment at Cluny, in France, where teachers in secondary schools are trained, has had to be closed, owing to a serious outbreak of typhoid fever. Just before the summer vacation one or two cases occurred, and the administration immediately broke up the college and the school attached to it, and sent the students and boys to their homes. The harm, however, seems to have been already done, as more than 150 of these young men and boys have been suffering from typhoid fever, several having died from it. On investigation, it was found that the foundations of the building were laid in a mass of infective material, and that the drinking-water was all contaminated. Dr. Rodet, of the experimental pathology department, has succeeded in cultivating typhoid bacilli from several samples of the drinking-water.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BOREHAM, W. TODMAN, M.D., has been appointed Honorary Physician to the Mildmay Home for Consumption, Torquay.

BURD, E. LYCETT, B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed Second Medical Visitor to the Private Asylums of Salop and Montgomery.

COOMBE, RUSSELL, B.A.Cantab., M.R.C.S., L.R.C.P. Ed., has been appointed House-Surgeon to the Devon and Exeter Hospital, Exeter.

COONEY, JOHN EDWARD, L.R.C.P.Ed., L.F.P.S.Glas., has been appointed Medical Officer for the Second District of the Fulham Union.

FERNIE, EDWARD, M.D. Univ. St. And., M.R.C.S., has been reappointed Medical Officer of Health for the Stone Urban Sanitary District.

FOX, RICHARD J., M.B., C.M.Edin., has been appointed Clinical Assistant to the Birmingham Borough Asylum.

MCGEAGH, JAMES PAUL, M.D., M.Ch.Qu.Univ. Irel., has been appointed Medical Officer for the Rural District of the West Derby Union, vice Fitzpatrick, resigned.

MYERS, ARTHUR T., M.D.Cantab., M.R.C.P., has been appointed Physician to the Belgrave Hospital for Children.

PERN, ALFRED, L.R.C.P.Lond., F.R.C.S.Eng., has been reappointed Medical Officer of Health for the South Stoneham Rural Sanitary District.

SHROFF, D. S. C., L.R.C.P.Ed., L.R.C.S., has been appointed Honorary Surgeon to the Royal Alfred Sailors' Home, Bombay, vice J. M. Barbour, M.B., C.M.Glas., resigned.

WILSON, THOMAS, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer of Health for the Wallsend Urban Sanitary District, vice Aitchison, whose appointment has expired.

WINGRAVE, THOMAS, M.R.C.S., has been appointed Surgeon to the City and East London Dispensary.

Digitized by Google

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary £150 per annum (with an allowance of £30 per annum for cab hire), and furnished rooms, fire, lights, and attendance.

BLACKBURN AND EAST LANCASHIRE INFIRMARY. — Junior House-Surgeon. Salary to commence at £30 per annum, with board, washing, and lodging.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C. — House-Surgeon.

CHELSEA, BROMPTON, AND BELGRAVE DISPENSARY, Sloane-square, S.W.—House-Surgeon and Secretary. Salary £95 per annum, with furnished apartments and an allowance of £20 for coals and candles for the use of the institution.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Registrar and Chloroformist. Salary £30 per annum, with an additional £20 if the post is held for twelve months.

LINCOLN UNITED FRIENDLY SOCIETIES' DISPENSARY.—Resident Medical Officer. Salary £300 per annum, midwifery and vaccination fees, coals and gas, with house free of rates.

LIVERPOOL INFIRMARY FOR CHILDREN. — Assistant House-Surgeon. Board and lodging in lieu of salary.

NORTH LONDON CONSUMPTION HOSPITAL.—Physician.

OWENS COLLEGE, Manchester.—Bishop Berkeley Fellowships. Value £100 for one year, and renewable for a second year.

ROTHERHAM HOSPITAL.—Assistant to the House-Surgeon. Rooms, commons, and washing, in lieu of salary.

ROYAL HANTS COUNTY HOSPITAL, Winchester.—House-Surgeon. Salary £100 per annum, with board and lodging.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road. — Junior House-Physician. Salary at the rate of £50 per annum, with board and lodging.

ST. THOMAS'S HOSPITAL.—Obstetric Physician.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Salary at the rate of £50 per annum, with board and lodging.

SUSSEX COUNTY HOSPITAL, Brighton.—Assistant Physician.—Assistant House-Surgeon. Board, lodging, and washing, but no salary.

TAUNTON AND SOMERSET HOSPITAL. — House-Surgeon. Commencing salary £100, with board, lodging, and washing in the house.

VESTRY OF ST. MARY, Newington.—Medical Officer of Health. Salary £300 per annum.

WEST KENT GENERAL HOSPITAL, Maidstone.—House-Surgeon. Salary £150 per annum, with furnished apartments, coals, gas, and attendance in the hospital.

Births, Marriages, and Deaths.

BIRTHS.

JACKSON. — On the 11th inst., at Garlenick, Grampound, Cornwall, the wife of Louis Pilkington Jackson, L.R.C.P., of a son.

MORTIMER.—On the 2nd ult., at the Royal Naval Hospital, Hong-Kong, the wife of Deputy Inspector-General E. T. Mortimer, R.N., of a son.

PORTER.—On the 14th inst., at Bow-road, the wife of J. F. Porter, M.D., of a daughter.

PIRRIE.—On the 14th inst., at Redcliffe-gardens, South Kensington, the wife of J. M. Gordon Pirrie, M.D., of a son.

MARRIAGES.

CLARK—WOOD.—On the 13th inst., at St. Martin's Church, Dorking, Arthur W. Clark, L.R.C.P.Lond., M.R.C.S., to Louisa Kate, third daughter of Thos. Wood, of Parsonage House, Dorking.

SMYTH—SUTCLIFFE.—On the 11th inst., at St. David's Church, Nass, Ross V. B. Smyth, M.A., M.D., to Emilie Grace, daughter of J. R. Sutcliffe, Hibernian-bank, Nass.

WHEELER—CHALK.—On the 13th inst., at St. Peter's, Dulwich-common, Albert Wheeler, M.R.C.S., to Mary Laura, only daughter of William Henry Chalk, of Barry-road, East Dulwich.

DEATHS.

EVANS.—On the 17th inst., after a protracted illness, at his residence, Bethune-road, N., Evan Evans, M.D.Lond., Staff-Surgeon, R.N., of Finsbury-pavement, aged 66.

JONES.—On the 1st ult., at Port Fairy, Victoria, Australia, Wm. Jones, M.R.C.S.Eng., youngest son of the late Richard Jones, M.D., of Kidderminster, and formerly Surgeon, 2nd R. N. B. Dragoons (the Scots Greys), in his 78th year.

LEFTWICH.—On the 13th inst., at 12, Grove-road, Highgate-road, N.W., Charles Harcourt Leftwich, M.R.C.S., L.S.A., aged 31.

PYNE.—On the 13th inst., at his residence, Royston, Cambs., Richard Pyne, Esq., M.R.C.S.Eng., J.P., for Cambs., aged 82.

TAYLOR.—On the 16th inst., at Lancaster, Harold Gilbertson Taylor, M.D., Assistant Medical Officer of the Royal Albert Asylum, aged 32.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, October 24.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE. — Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Treves: The Diagnosis and Treatment of Chronic Intestinal Obstruction. — Dr. B. W. Richardson: Short Note on Methylal (with a specimen). — Mr. Marmaduke Sheild: A case of Acute Glossitis in a Child, complicated by Trismus.

Tuesday, October 25.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

THE PARKES MUSEUM OF HYGIENE. — 8 P.M. Mr. J. F. J. Sykes: General Powers and Duties of Inspectors of Nuisances; Method of Inspection.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. John D. Malcolm: The Condition and Management of the Intestine after Abdominal Section considered in the light of Physiological Facts.—Mr. W. Arbuthnot Lane: (1) On the Mode of Fixation of the Scapula, suggested by a Study of the Movements of that Bone in Extreme Flexion of the Shoulder-joint, and its Bearing upon Fracture of the Coracoid Process; (2) An Undescribed Method by which the Superjacent Weight of the Body is transmitted in a United or Ununited Fracture of the Neck of the Femur through an Acquired Ilio-femoral Articulation, and the Bearing of the Principle involved upon the Surgery of the Hip-joint.

Wednesday, October 26.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 3 P.M.; Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

HUNTERIAN SOCIETY.—8 P.M. Dr. Port: On Antipyrin.—Dr. Turner: A case of Purpura.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M.—Specimens will be shown by Mr. Lawson Tait, Dr. Edis, Dr. G. Granville Bantock, and others. Mr. Lawson Tait: Three cases of Intra-peritoneal Hæmorrhage in which the condition was due to Ruptured Tubal Pregnancy successfully dealt with by Ligature of the Broad Ligament.—Dr. Bedford Fenwick: On the Use of Blood-testing in Gynecological Practice Council at 8 P.M.

Thursday, October 27.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

BIRDS' INSTINCT REGARDING FRUIT.

THE fruit in Chili and other parts of South America is said to have been this year left entirely untouched by the birds, and to have occasioned the death of both sheep and cattle when given to them in large quantities. These observations are referred to in the *Archivo del Pacífico di Medicina y Cirugia* as tending to show that the instinct of birds with respect to the wholesomeness of fruit is, as Michelet remarks in his work on birds, frequently a worthy guide for human beings to follow. It is possible that the difference in the fruit of different years may have something to do with the etiology of outbreaks of cholera.

J. M.—We have nothing in this country comparable with "Schmidt's Jahrbuch," to which "Braithwaite's Retrospect" is the nearest approach.

Mr. F. C. Wood.—The same qualifications are required as for Poor-law appointments—i.e., a qualification in Medicine and Surgery. Under special circumstances one such qualification is accepted.

Dr. Charteris.—Yes.

LARYNGISMUS STRIDULUS.

To the Editors of THE LANCET.

SIRS,—In the kindly notice of my paper, reprinted from the "Archivio de Patologia Infantile" of Naples, "Sul Laryngismo Stridulo," &c., in yesterday's issue, your reviewer says: "We notice that cod-liver oil is not mentioned, which in our opinion should be the practitioner's sheet anchor." Now, here he has evidently overlooked the remarks on page 17 of the paper: "L'olio di fégato di merluzzo a dosi non troppo alte può essere dato; bisogna esaminare le feci, giacchè se l'olio appare gallegiante sopra la superficie, la dose dourebbe essere ridotta." Had I, indeed, omitted to mention so valuable an agent in the treatment of these cases I should have been unworthy of any favourable notice; but, in fact, I not only acknowledged its value, but agree almost entirely with your reviewer's estimate, and I also called attention to a very important point in the precaution necessary during its exhibition of watching the stools; for a long experience has convinced me that, in the majority of children's cases in which this oil is given, a large proportion passes unchanged through the bowels, and is not merely useless, but positively injurious by its relaxing effect. The true plan is to reduce the dose until the oil is no longer visible on the motions.

I trust that, when your reviewer's attention has been called to this, he will withdraw the stricture.

I am, Sirs, yours very truly,

Manchester, Oct. 16th, 1887. W. H. BARLOW, M.D.

SWALLOWING A COIN.

To the Editors of THE LANCET.

SIRS,—On reading the note on the above subject by "H. F. S." in your last issue I thought the following might be of interest.

A female child, aged three years, on Dec. 15th, 1886, swallowed two farthings. The next day the patient could only swallow small quantities of food at once, and that with pain, fluids causing more difficulty than solids. The mother was of opinion that one of the coins had stuck in the child's throat; but nothing could be detected, any laryngoscopic inspection being impossible, owing to the great fright of the little patient. Air entered freely into both lungs, but with each inspiration was heard a wheezy sound, more marked when asleep, and still more so when excited. These symptoms persisted, the child could take but little food, became pale and thin, and developed a cough. There were still no physical signs in the lungs, and nothing could at any time be felt externally. On Jan. 24th, 1886, the farthing passed per anum, and all symptoms ceased. The other farthing caused no inconvenience, but was not passed per anum till nearly five months after being swallowed—viz., on May 7th, 1886.—I am, Sirs, yours truly,

J. LANGTON HEWER, M.D., F.R.C.S. Eng.

Brownswood-park, N., Oct. 15th, 1887.

To the Editors of THE LANCET.

SIRS,—I had a similar case to that recorded by "H. F. S." in your last issue, which may interest him and other readers.

I was called on July 2nd of this year to a little girl, aged four years, who had swallowed a new bronze halfpenny. Purgatives were forbidden, and a dry diet prescribed. The bowels acted regularly once a day until July 11th, when the coin was evacuated, locked up in a mass of hard faeces. Thus it took only two days longer to pass than in the case reported by your correspondent. The coin was coated quite black with cupric sulphide. As it was a nearly new bronze one, I obtained another of the same date, and found that the one which had been swallowed weighed a grain and a half less than the other. Of course, the loss of weight goes for very little, as the one may have been slightly more worn than the other; but, as I have observed, they were both new. The child suffered no inconvenience.

I am, Sirs, yours truly,

Oct. 17th, 1887. L.R.C.P.

WELL-TO-DO MEMBERS OF FRIENDLY SOCIETIES AND MEDICAL ATTENDANCE.

Dr. Aldersea.—We are not sorry that this question has been raised in a leading lodge, where the members and the medical officer understand and respect each other, as in this case; and we shall look with interest to the result of their meeting, and with some confidence that it will be good and worthy of the interests concerned.

Rev. Walter Wilson.—We hope shortly to give some information about the various services and posts which are open to medical men. Our correspondent will find a great deal of valuable information in Dr. Dyer's little work, "The Young Doctor's Future" (Smith, Elder, and Co.); also in the introductory pages of the Medical Directory (Churchill).

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—A slight inaccuracy occurs in your report of my case in your last issue, page 759, though it is hardly perhaps worth noticing. The patient was not seen on July 11th by Mr. Fawsitt as reported, but by myself. I was on a visit to Oldham at the time, and naturally took the opportunity of seeing the boy again.

I am, Sirs, yours faithfully,

Southport, Oct. 18th, 1887. JOHN J. WEAVER (late House-Surgeon).

A BELGIAN MEDICAL AID SOCIETY.

A CORRESPONDENT of a Belgian medical journal complains that a society which calls itself "La Santé" is attempting to obtain medical services for its members for a very inadequate sum. This society appears to correspond to several benefit and insurance societies possessing a medical aid branch which exist and flourish in this country, and against which, as long as they confine their operations to the poor, there is nothing to be said. The tariff of "La Santé" is as follows:—Medical attendance, 3 fr.; confinements, 5 fr.; medicines (from a pharmacist), 4 fr. There would appear to be no restrictions as to the class of persons who may join "La Santé." Notwithstanding the poor rate of remuneration, the prospectus, which seems to have been largely advertised, claims that it has on its staff the *best* doctors, dentists, and pharmacists!

Mr. A. V. Dyer.—Quinine is well known as a uterine stimulant.

FIRES IN THEATRES.

To the Editors of THE LANCET.

SIRS,—"Practice makes perfect"; and the converse is true—nothing can be done well without practice. We initiate our soldiers and sailors into the art of war by sham fights, and why should we not learn to deal with conflagrations in theatres by rehearsing sham fires? If that were done to-night at almost any theatre in the kingdom, I doubt not that we should find that the gas, the escape of which from melting pipes is the real source of danger and sole cause of rapid destruction, could not be turned off at the main; that candles, which ought to light the corridors, so as to obviate darkness and consequent panic when the gas was turned off, were conspicuous by their absence; that the special doors of exit in case of fire were rusted up and could not be opened, or that the man in charge had gone to the seaside with the key in his pocket; that the iron screw intended to shut off the stage from the auditorium would not work; that the fire hose on the stage was useless, and the extincteurs all dried up. It has been so, and will be so until care is taken from day to day to see that everything is in order, so that it may be used on the instant should danger arise. Let the proprietors of theatres announce the rehearsal of sham fires at the close of a performance, invite spectators, or charge, if they please, for admission. Let them show that whatever happened they were prepared to fight the terrible demon the moment he appeared, and that, win or lose in the encounter, there would always be time for the audience to clear out without those ugly rushes which have caused so many deaths. Let the public feel convinced that those who are responsible for such matters had everything in readiness, and were prepared to meet any emergency; that the right men were in the right place, and ready when wanted; that the blazing stage can be instantly shut off from the body of the theatre by an iron screen; above all, that the gas could be turned off in a moment without involving absolute darkness, and we can go to the theatre in comfort, well assured that no harm can come to us, except from our own folly if we join in a senseless stampede for the exit—a stampede which would not occur if the public felt and were thus taught they could sit still or file out in order without running the risk of suffocation or roasting alive. I am, Sirs, your obedient servant,

Oct. 17th, 1887. C. B. T.

P.S.—The volume of gas in a theatre is enormous. I see a recent writer to the *Spectator* states that he has seen a small gas-pipe spring 10 ft., a column of flame which ignited an inch plank in twenty seconds. It was the flames mixed with volumes of escaping and ignited coal-gas which reached the gallery in the Exeter Theatre within five minutes. All theatres should be directly connected with the fire brigades, so that no time may be lost in summoning help; and a couple of baths filled with water placed at the sides, so that if an actress's dress caught fire she could jump in at once. The fire rehearsals should take place once a week, and insurance offices refuse to have anything to do with any theatre in which this was not done.

"CORONERS' INQUESTS."

To the Editors of THE LANCET.

SIRS,—Mr. Gray's experience of coroners' inquests is surpassed by my own. In my last three cases no medical evidence whatever was given, and no post-mortem examination held. The coroner and his twelve jurymen decided in each case that deceased had died from "natural causes." I fancy most medical men would characterise such a decision as rash—if they wished to put it mildly. The first case was that of a young man who, after working in his garden and subsequently playing cards at his club, complained for the first time of illness (headache), started for home, and fell down and died almost immediately; no medical man saw him before death. He was a strong, healthy man twenty-one years of age, and was not suspected of disease. In the second case a middle-aged man left the harvest field, saying he did not feel well, went home, locked himself in his bedroom, and was found dead later. The third case was that of an old man who complained of cramping pains in the body, left his work, was ill all night, and died next morning without medical attendance. The only thing that exercises my curiosity is why coroners require a jury at all, and why they go through the solemn farce and mockery of an inquest when they exclude the only evidence that can decide the question.

I am, Sirs, yours obediently,

Oct. 6th, 1887. COUNTRY DOCTOR.

HELP FOR UNSUCCESSFUL MEDICAL MEN.

An Old Correspondent wishes us to advocate a scheme or institution for the relief of assistants or others who have not been able to save or lay by anything. He observes that the wealth of Sir Erasmus Wilson and Mr. Quain was not left for this purpose. We must remind him that there is an excellent institution in London for the relief of orphans and widows of medical men, and that it is, strangely, unsupported by many men to whose families such a provision would be an unspeakable comfort. Self-help and providence are indispensable in our profession, as in all others.

L.R.C.P. Lond.—If our correspondent is thoroughly acquainted with either German or Latin, he may try almost any German university. If not, he may write to the Dean of the Medical Faculty of the University of Erlangen, where, we believe, an interpreter may be permitted. The University of Liège might perhaps admit an English medical man. Its requirements are much the same as those of Brussels. We cannot say whether an interpreter is allowed. The Dutch university of Arnheim permits its examination for M.D. to be conducted in English. It should be remarked that there is no reason to expect that the examination in any of these cases will be easier than in Brussels.

Interrrogans.—Jeffrey Bell's book in Cassell's series.

"CATARACT OPERATIONS."

To the Editors of THE LANCET.

SIRS,—In your issue of last week a correspondent, "Sapo Mollis," asks for the "usual percentage of success in cataract operations." To answer this question it is necessary to know what is meant by "success"; for it might be applied to all those cases in which the eye is not lost from panophthalmitis following on the operation, or to those cases in which vision is improved in any degree, however small, on what it was previously; or the word "success" may be retained for a still higher standard, and only used for cases in which the patient is enabled to read and write. Dr. C. Schweigger, writing on this point in the "Archives of Ophthalmology," vol. xvi., No. 3, in a paper entitled "The Operations for Primary and Secondary Cataracts," which has been translated by Dr. Cornelius Williams, says: "V. Graefe was accustomed to reckon as a perfect result a case in which V. = $\frac{1}{10}$. This I do not think quite justifiable, since V. $\frac{1}{10}$ is not sufficient for reading and writing;" and he goes on to say that he takes as his standard of success.

"Sapo Mollis" next asks for "the percentage of success from the hands of all operators in the Moorfields Eye Hospital for the last five years." I have only had time to collect the figures for the last four years; they are as follows: Of unselected cases of extraction of senile cataract, in nearly all of which a modified Graefe's operation was performed, there were: In 1883, 225 cases, of which 14 suppurated; in 1884, 241 cases, of which 8 suppurated; in 1885, 264 cases, of which 3 suppurated; in 1886, 285 cases, of which 7 suppurated,—making a total of 1015 cases and 32 suppurations, or 3·15 per cent. If, however, only the last three years be taken, the percentage is much lower; from 1884 to 1886 inclusive, there were 790 cases, of which 18 suppurated, or 2·28 per cent.

To obtain the percentage of cases that obtain useful vision is practically impossible, as so many eyes are lost from different causes after patients leave the hospital. Thus a case that has lost vitreous and been discharged with fair vision, may a few weeks later get a detachment of the retina, or floating opacities in the vitreous, which renders it practically a lost eye; or, again, a case followed by an attack of iritis which has quieted down may have it again lighted up on leaving the hospital, and end in a closed pupil. I certainly think that a percentage of seventy-four that can read and write is a fair average, and not much below that obtained at Moorfields.—I am, Sirs, yours faithfully,

R. TREACHER COLLINS,
Senior House Surgeon, Royal London Ophthalmic
October, 1887. Hospital, Moorfields.

SYPHILIS IN BOSNIA AND THE HERZEGOVINA.

DR. GLÜCK mentions, in a report on syphilis in Bosnia and the Herzegovina, published in the *Przeglad Lekarski*, that hereditary syphilis is very common among the rural population of these provinces, and that it is treated in a very heroic and improper manner. Two chief forms of treatment are commonly practised—the "mild," which consists of making the persons affected smoke cinnabar (sulphide of mercury), and the "strong," which implies the administration by the mouth of mercurial pills. By the way, smoking cinnabar is a well-known remedy amongst Indian hakims for syphilitic ulceration.

New York.—In reply to a query as to practice in the State of New York, we would say that a diploma must be obtained from some medical college in that State. Our correspondent may with advantage refer to Wooton and Winslow's Guide to the Medical Profession (Upcott Gill), or he may write to the Dean of the College of Physicians and Surgeons, New York, who will doubtless inform him of the terms on which an English medical man can be admitted to examination. Most of the other States accept British qualifications.

Mr. F. Treves.—Yes.

Digitized by Google

ABUSE OF HOSPITALS BY THE WELL-OFF.

A CORRESPONDENT of the *Bristol Times* asserts, on the authority "of one of the surgeons," that actually one of the Judges lately underwent treatment at one of the great London hospitals, and was cured there, but made no present to the institution. We are slightly incredulous on this subject, though it cannot be denied that in every rank of society there is a strange willingness to get medicine for nothing, or on shabby terms.

M.B. has not enclosed his card.

A CAUTION TO SECRETARIES AND CLERKS OF HOSPITALS AND OTHER CHARITIES.

To the Editors of THE LANCET.

SIRS,—Will you allow me to warn my colleagues against a man who is now calling at hospitals &c., stating that he has been sent by the editor of a well-known "daily" for a couple of reports which the editor wishes to send to two benevolent persons, whom he names, and who are desirous of making donations. After this plausible opening he asks for further papers for similar purposes, which he assures his interlocutor will be most judiciously used by the editor, and having thus increased the interest already aroused, he asks the small sum necessary for postage. The man is fair, between thirty and forty years of age, and, when I saw him, with a beard and moustache.

I am, Sirs, yours faithfully,

Oct. 18th, 1887. A HOSPITAL SECRETARY.

*** We have received a letter to the same effect from the Lady Superintendent of the Hospital for Women and Children, Lupus-street, S.W.—ED. L.

SWALLOWING SPECTACLE GLASSES.

To the Editors of THE LANCET.

SIRS,—With reference to the note in your last week's issue by "H. F. S.," headed "Swallowing a Coin," the following may appear interesting.

A male lunatic swallowed both glasses of an ordinary pair of spectacles at 2 P.M. on Friday, the 14th inst. They were passed together about 8 A.M. on Sunday, the 16th—i.e., forty-two hours afterwards. No inconvenience resulted. Treatment consisted in the liberal administration of puddings made of farinaceous food. I am, Sirs, yours faithfully,

Oct. 18th, 1887. J. B.

ABSTRACT OF

A Lecture

ON THE

ANTISEPTIC TREATMENT OF WOUNDS,

Delivered to the Students of the Bristol Medical School on July 12th, 1887,

BY W. J. PENNY, F.R.C.S.,

ASSISTANT SURGEON TO THE BRISTOL GENERAL HOSPITAL.

GENTLEMEN,—Owing to Mr. Keall's temporary indisposition and inability to do so, he has invited me to bring before you the subject of "The Aseptic Treatment of Wounds and Practical Antiseptics." By the former is meant that process by which active ferments are excluded from wounds; and by the latter, not only this method, but also all processes which cause the destruction or retard the development of these active ferments when they have gained access to wounds.

You are all probably aware that the putrefaction of discharges and the various diseases that infect wounds are primarily due to micro-organisms admitted from the atmosphere or other external agency. For all practical purposes we may consider that these micro-organisms reach the wound directly from the outside, though in some rare instances they may reach it through the circulation or some of the various channels communicating with the surface of the body. For putrefaction, besides the micro-organism, which is the essential part, three main factors are necessary—firstly, a material to putrefy; secondly, a certain amount of heat; thirdly, a certain amount of moisture. Each of these factors has a great practical bearing on surgery; in the total absence of either, putrefaction is impossible; but there are certain infectious wound diseases, notably erysipelas and others due to pathogenic organisms—i.e., those which have the power of multiplying in the body—that will develop in spite of the almost entire absence of some of these factors, but, in the present state of our knowledge, we may say never in the absence of their specific micro-organisms. We will now discuss these factors *seriatim*.

The material to putrefy. Any dead organic matter, or that in a low state of vitality, is a fertile hotbed for the development of putrefaction. The lower the state of vitality of a tissue, the more prone is it to putrefy; but it will not putrefy unless the other essentials of the putrefactive process are present. A healthy living tissue—for instance, the muscle or mucous membrane of a strong, healthy man—has a great power of resisting putrefaction in spite of the presence of the essential factors; but lower the state of vitality of the structure by irritant, by injury, or by disease, and then expose it to the same influences, and you are extremely likely to get the process developed. Blood, serum, urine, and other materials formed in the body have a great tendency, when removed from it, to putrefy, and have also this tendency in a lesser degree when still retained in the body, but outside their natural receptacles, if micro-organisms gain access to them. It is, however, an interesting fact that healthy living tissues have not only the power of resisting putrefaction in themselves, but their influence extends in a slight degree to a layer of either of these fluids in contact with them or between their cut surfaces. This is well seen, as Sir Joseph Lister has pointed out, in wounds of the face. In this region, the parts as a rule are freely supplied with blood—consequently in a high state of vitality,—and thus strongly resist any tendency to putrefaction of the fluids between the lips of the wound. This preventive influence does not extend through a very thick layer of lymph or blood; hence the importance of the practical rule: Ensure accurate apposition of the cut surfaces and free escape of discharges.

As regards the second factor—a certain amount of heat. It is found that the temperature of the body—98° to 99°F.—is very favourable to the development of putrefaction. The factor is always present, and cannot be got rid of, except perhaps to a slight extent superficially, by the application of cold to the surface of a wound; this, however, is rarely advisable, at any rate to lower the temperature of the part below that suitable for the development of micro-organisms.

The next factor—a certain amount of moisture—is always present, and cannot entirely be removed. We can, however, do this to a certain degree in wounds, by providing very free drainage, that all discharges may be removed from the damaged or unhealthy tissues. No wound can be inflicted without damaging to a certain extent the tissues involved. The sharper the instrument, and the cleaner the cut, the less damage is there inflicted; but the more contused and torn the wound, the greater is the damage, consequently the lower its vitality, and hence the greater necessity for free drainage. There is also another method of obtaining dryness of wounds, which has been specially recommended by the late Mr. Sampson Gamgee of Birmingham, and that is by the use of dressings with a special absorbent power: prepared wools with all greasy matters removed from them. The open method of treatment of wounds adopted some years ago, and which at that time proved more satisfactory than the dressings then in vogue, to a certain extent fulfilled this condition, by permitting evaporation of the fluid parts of the discharges; the residue, being concentrated, was less fitted for the development of micro-organisms, and the dry crusts or scabs formed a mechanical as well as a chemical obstacle to their entrance. Pasteur found years ago that by concentrating his fluids the development of micro-organisms was retarded. This fact is taken advantage of by many manufacturers, as, for instance, in the preparation of condensed milk. This open method of treatment, I need hardly tell you, was most uncertain in its results. It resolved itself into a race between the evaporation and scabbing process on the one hand, and the development of germs on the other. Among auxillary measures for obtaining dryness of wounds I may mention elevation of the part; this, by causing a slight contraction of the vessels, lessens the blood pressure and effusion in the injured region, and also promotes venous and lymph return. Uniform elastic compression acts in much the same way. Absolute rest prevents disturbance of the blood clots in the vessels, and also lessens the amount of serous effusion.

Now we come to the last and most important—in fact, the essential—factor in causing wound infection and putrefaction in wounds, with their consequences, pyæmia, septicæmia, and such-like diseases: the admission and development of micro-organisms. Sir Joseph Lister's name will be for ever associated with the revolution in surgery occasioned by the recognition of this great principle. The exclusion or destruction of these organisms forms the guiding principle of antiseptic surgery. It matters not what agents are used, consistently with the welfare of the patient, provided the principle is carried out. By measures founded on it hospitals have been changed from hotbeds of infectious diseases to a healthy state where an infectious disease is the exception. Almost all wounds can be treated with absolute freedom from infective wound diseases by carrying out treatment based on this principle, even if all the other essentials of putrefaction are present; but I need hardly say that if you ensure the absence of the other factors you make assurance doubly sure. It matters not how imperfect the drainage, how low the state of vitality of the part, no matter how damaged, even to absolute destruction, if you can prevent the entrance of micro-organisms, or, if they have entered, remove or destroy them in the wound, you can certainly avoid putrefactive changes in it. Attention to other details may also be necessary to ensure rapid healing; but the absence of this one alone will certainly prevent putrefactive changes and septic diseases, and will also allow the dead or damaged tissue to be revivified, the quantity capable of being so depending on the vital powers of the patient. I have over and over again seen masses of tissue destroyed by injury, to all intents dead, gangrenous patches, gradually replaced by new tissue, not broken down and discharged as sloughs, but replaced by new tissue in the same way as a blood clot or piece of catgut in an aseptic wound. As this is a fact which can often be verified in the wards of our hospitals, we are justified, if the parts can be made aseptic, in giving the patient every chance of recovery before resorting to removal of the injured part, knowing that under these circumstances delay is not dangerous. One case I remember particularly, that of a young man whose upper arm was crushed by machinery. The part was severely mangled, the bone splintered, the main artery and

Digitized by Google

veins lacerated, the central parts of the biceps muscle torn away, and the whole of the skin of the upper two-thirds of the upper arm destroyed or stripped away from the muscles, except a piece two inches wide at the back. There was absolute loss of pulse in the radial and ulnar arteries. This patient made a most satisfactory recovery with a useful arm. The brachialis anticus muscle hypertrophied to supply the function of the lost biceps. Large portions of skin and other tissues lost their vitality and became gangrenous; they did not, however, break down or come away as sloughs, but were gradually replaced by new tissue. No radial or ulnar pulse was felt at the wrist for more than nine months after the accident. About six months after the accident, during the winter of 1884-85, several fingers of the hand on the injured side became frost-bitten, but ultimately recovered. This is not a solitary case. I have seen and treated many very like it.

Now let us consider how these micro-organisms gain access to wounds. Formerly the atmosphere was considered one of the most active means of wound contamination. In all air, however pure, except perhaps on the tops of some very high mountains, micro-organisms exist, and have the power of causing putrefaction of various fluids, vegetable infusions, &c. In hospital wards, where putrid wounds and infective wound diseases are sometimes congregated, besides the ordinary organisms found in the air, others peculiar to these diseases are present, and have the power of developing in wounds if suitable conditions are present in them. Here are two bottles of urine taken from the same individual fifteen months ago; the same precautions were observed in both, but one of them was afterwards exposed to the air, and you see by its muddy appearance and putrid odour that changes have occurred in it. The other has been kept from the air; here it is, you see, quite unchanged, and as clear as on the day on which it was passed. It was from the results of an elaborate series of experiments like this that Sir Joseph Lister was led to invent the spray, the object of which was to exclude germs by keeping the wound in an antiseptic cloud. The results which followed its introduction were most satisfactory. By a later series of experiments, Sir Joseph found that blood clot, pus, and other fluids were not quite as prone to putrefy from exposure to the ordinary air as vegetable infusions, and also that the inhibitive action of living tissues was a great power in preventing putrefaction. Having thus proved by experiment that the spray was unnecessary, he has, I believe, entirely discarded it. For my own part, I have had such satisfactory results with the spray that I feel loth to dispense with it, especially if there should happen to be an infectious case in the ward, which I am pleased to say is a very exceptional occurrence. I also use it most carefully in operations on large cavities, especially on the pleura in cases of empyema. In these cases large quantities of air are sucked in during inspiration, and it appears to me not at all unlikely that micro-organisms capable of developing might be admitted and lodge in a recess out of reach of lotions. The resisting power in these cases is slight, and the less the resisting power the greater should be the precautions taken to guard against any possible source of contamination Various materials have been used in the spray. Carbolic acid has been the most efficient. Thymol was used, but was a less powerful germicide. Mr. Mayo Robson of Leeds has used a dry spray of eucalyptus. He states that it acts most satisfactorily, is efficient, does not chill the patient, or obscure the field of vision of the operator.

A most important means of preventing putrefaction in wounds, especially if the spray is not used, is free ventilation and avoidance of contamination of the atmosphere by the most scrupulous cleanliness of everything in the room. All excreta should be removed as soon as voided. The drains should be in thorough repair; they should be properly trapped, and ventilated from the outside. To show how powerful a means of preventing wound infection we have at our disposal, I may state that five years ago the drainage and ventilation of the Bristol General Hospital were found to be in a most unsatisfactory condition. Drain smells were prevalent; and at one time, out of 130 patients in the house over seventy had diarrhœa. In spite of this, no cases of pyæmia or septicæmia developed, and only one case of erysipelas, which was traced to infection from an unpurified probe. The dangers of wound infection in this atmosphere, which were very great, were guarded against effectually by strict antiseptic precautions. The intestinal infections, however, necessitated the closure of the hospital, and a complete overhauling of the drains and ventilation, which was carried out in a most liberal spirit by our committee. The results obtained during this insanitary period I watched with interest, and to my mind it afforded a convincing proof of the efficacy of the aseptic system of treatment.

The next method by which germs gain access to wounds is from the surrounding skin, instruments, sponges, and the operator's hands. All unpurified skin teems with micro-organisms, especially in a part where two surfaces of skin approximate each other, or where sweat glands are largely developed, as in the groin, perineum, or axilla. To purify the skin thoroughly, it should be washed with warm water and soap, and after that well bathed with a 5 per cent. solution of carbolic acid. This solution has a great power of penetrating the skin or any greasy materials, and therefore is specially suitable for cleansing purposes. It requires a certain time to act properly. In the regions mentioned it is a good plan to purify the parts an hour or two before operation, and then fasten on a piece of lint soaked in the carbolic solution. The operator's hands and the instruments should be purified, either by prolonged soaking in carbolic, or by first washing with soap and water, and then douched with carbolic. No instrument should be used that has been merely dipped in the carbolic solution. Keummell of Hamburg has shown that a perfectly new instrument, highly polished, is not purified by immersion for two minutes in a 5 per cent. carbolic solution; ten minutes, however, suffice to purify it. Any instruments were purified by first washing with potash soap and warm water, and then immersed for one minute in a 5 per cent. solution of carbolic, or a 1 in 1000 solution of corrosive sublimate. The same remarks apply to the operator's hands. Sponges should be purified after use by soaking and repeated washings in soda-and-water, and after that well rinsed with hot water, and kept in a 5 per cent. solution of carbolic until again required. New sponges, after removal of the sand, should be soaked and washed alternately several times in a dilute solution of hydrochloric acid and soda solution, then well washed in warm water and kept in the carbolic solution. During the operation, or for washing instruments and skin after the initial purification, a 1 in 40 solution of carbolic is sufficiently powerful; stronger solutions cause needless irritation. A lotion of corrosive sublimate, 1 in 1000 or 1 in 2000, is very effectual, and has less tendency to irritate the skin than carbolic acid; besides this, it is cheaper, less volatile, and more portable. For mild antiseptic lotions, saturated solutions of boracic acid and salicylic acid are used. To purify foul sores or sinuses use a solution of chloride of zinc (40 gr., water 1 oz.); or an emulsion of boracic acid, iodoform, and eucalyptus oil. Boro-glyceride is a very useful and mild antiseptic.

Dressings.—The chief points required in a dressing are, that it should be well charged with an efficient antiseptic, which is retained in it at the temperature of the body for a sufficient time; it should be very absorbent, elastic, comfortable to the patient, unirritating to the skin, and cheap. Carbolic gauze is a fairly good dressing; but as carbolic acid is very volatile, it requires to be mixed with resinous material to enable it to be retained sufficiently long in the dressing. This interferes with the absorbent powers of the gauze, causes it to adhere to the patient's skin, and in some cases to irritate it unduly. Eucalyptus gauze has the advantage of being less irritating to the skin than the carbolic; but Watson Cheyne has found that it is less powerful as an antiseptic agent. The gauze deteriorates rapidly by keeping, on account of the excessive volatility of the eucalyptus. Salicylic wool and jute are more comfortable and more absorbent than the gauze, but the powder causes intense irritation of the nose. Sal alembroth wool is very elastic and comfortable, and contains a large quantity of a powerful antiseptic. The sublimated wood-wool wadding is extremely absorbent and comfortable to the patient. Iodoform and borated wools and lint are mild antiseptics, very useful for external superficial sores. For foul ulcers I have found pads of moss litter, either plain or impregnated with boracic acid or iodoform, a very cheap and effectual dressing, keeping the sores dry, clean, and free from smell. Vaseline or lanoline, impregnated with either boracic acid, iodoform, eucalyptus, or corrosive sublimate, make useful antiseptic ointment. Glycerine and carbolic, or carbolised oil, are also used. It makes little difference what form of antiseptic is used, provided it is sufficiently powerful and is intelligently applied in accordance with the antiseptic theory. The protective—a specially prepared oiled silk—

Digitized by Google

protects the wound from the irritation of the antiseptic. When used it must be well over-lapped by the antiseptic dressing, and where this cannot be done it had better be dispensed with. A great advantage is that it prevents the dressing sticking to the surface of the wound; its bland, smooth, unirritating surface certainly favours the healing process. The drawback to its use is, that it keeps the wound moist, thus favouring putrefaction if germs gain an entrance. The moist condition causes irritation of some sensitive skins, especially of the feeble skin in the neighbourhood of ulcers. I have recently endeavoured, by using a perforated protective, to keep the dressing from sticking to and irritating the surface of the wound, and at the same time to keep it in as dry a state as possible.

Drainage.—The opening for the escape of discharges should be provided, when possible, at the most dependent part; if not, a certain amount of fluid must accumulate to the level of the opening before it runs off. For large wounds or large cavities indiarubber tubes provide the best drainage; in some cases they should be as large as one's finger. For smaller wounds, strands of horsehair or a strip of protective are sufficient. We must always bear in mind that either of these materials is a foreign body, and should be dispensed with as soon as possible. Retention of discharge is, however, a much greater evil. Each case must be judged on its own merits. As a rule, in a clean-cut wound in healthy tissues, ample drainage is required for the first day; it can gradually be lessened, and entirely dispensed with on the third or fourth. In other cases—as, for instance, a large abscess cavity communicating with diseased spine—the tube may not require to be shortened for nine months or a year. In these cases the indications for shortening a tube are its extrusion by the granulation or contraction of the cavity, combined with signs of repair of the part, and no evidence of accumulation of discharges, such as pain, pyrexia, increased pulse, the formation of a fluctuating swelling, or purulency of the discharge. In some cases special tubes made of metal are required.

To arrest hæmorrhage, torsion or forcipressure should be used for small vessels; for those of the size of the radial or larger arteries catgut had better be employed. The best is the sulphurous acid gut, prepared according to Sir Joseph Lister's directions, by first soaking in chromic acid solution and then in sulphurous acid solution. This is very strong and reliable, and a fine strand can be used for large vessels. If large-sized chromicised gut is used just under the skin, the knot is apt to cause irritation and possibly suppuration. The sulphurous acid catgut is also useful for buried sutures, the object of which is to bring together and keep in apposition the deeper parts of a wound; this prevents the effusion and accumulation of discharges, and sometimes accelerates the healing process. For large pedicles, as in ovariotomy, Chinese twist, a pure silk, may be used after soaking for a quarter of an hour in 5 per cent. carbolic. Strong catgut is also used.

Sutures.—Silk impregnated with 10 per cent. carbolic in bees'-wax is generally employed. Silver wire is non-absorbent and unirritating. Catgut may also be used, and can be left *in situ* until the inner parts of the suture are absorbed. For small wounds, carbolised but otherwise unprepared catgut had better be employed, the external parts can be brushed away in a few days. The sulphurous acid gut will not be absorbed for a month or six weeks. The button suture is extremely useful in bringing the widely separated edges of a wound together; being placed at some distance from the edges, it does not interfere with the healing process. Sutures should never be used to drag the edges of the wound together; the skin contained within them should not be puckered, or that outside them furrowed; both are indications of undue strain, and both retard healing, besides causing pain to the patient as well as the risk of exciting inflammatory disturbance in the neighbourhood. Especial care is required in introducing sutures into damaged or unhealthy tissues; the slightest tension must be avoided; better leave the wound widely gaping.

All dressings should be kept in tin boxes. This prevents any risk of their contamination, and retards evaporation of the more volatile ingredients. It is a good plan to keep a wide-mouthed bottle filled with a volatile antiseptic inside the box with the dressings. The jaconet mackintosh is a convenient application outside the dressings. It prevents the discharges coming directly in contact with and being contaminated by the air, and makes them traverse a long line of the antiseptic before doing so. It also keeps the deeper dressings nicely in place. The drawback to its use is that it confines the perspiration and the more watery parts of the discharges, and thus keeps the wound moist. The elastic bandage fastened lightly round the edges keeps the dressings in contact with the skin, and prevents a large quantity of air being sucked directly into the wound by the movements of the patient. If the elastic bandage is applied tightly it causes pain, and possibly œdema of the distal parts.

To recapitulate the antiseptic or aseptic treatment of wounds: 1. Arrest all hæmorrhage, thus preventing the accumulation of blood clot, the nidus for development of micro-organisms. 2. Remove all foreign bodies, such as dirt, detached pieces of bone or tissue. 3. If foreign bodies or micro-organisms have gained an entrance, purify thoroughly with an efficient antiseptic. 4. Provide very free drainage, in the most dependent part if possible. 5. Bring the parts into accurate apposition, like to like; but carefully avoid tension, especially of the edges of the wound or in damaged or unhealthy tissues. 6. Apply a large dressing sufficiently impregnated with a reliable antiseptic, and very absorbent and elastic. 7. Bandage firmly and evenly to get elastic compression. 8. Elevate the part to lessen the blood pressure and effusion while the vessels are weak from the injury. 9. Give absolute rest; change the dressing as little as possible. Visible discharge is the indication if the dressing is reliable. 10. Attend to the general health and give a free supply of good food and fresh air, in this way promoting the resisting and healing power of the tissues. Recognition of these principles, their study and adoption, are of as much or more importance to a surgeon than a knowledge of anatomy or manual dexterity. By them you take surgery out of the region of chance and make it much more an exact science. If you happen to have an infectious case, let me impress upon you, gentlemen, not to look on it as an unavoidable accident, but recognise it as being due to some mistake in your chain of treatment, to be found out and in the future guarded against. None of us are free from mistakes or accidents; the best surgeon is he who has the least number, who recognises that he is not infallible, but strives to discover his mistakes, and from them learns lessons for his future guidance.

A CASE OF PERNICIOUS ANÆMIA,

APPARENT RECOVERY; RELAPSE; DEATH.

By W. TYRRELL BROOKS, B.A. OXON., M.B. LOND.,
LICHFIELD LECTURER IN CLINICAL MEDICINE IN THE UNIVERSITY OF OXFORD.

MRS. G——, aged thirty-eight, came as an in-patient to the Radcliffe Infirmary, Oxford, on December 27th, 1884. She gave the following account of her illness: About twelve months ago she began to lose blood from the anus. The hæmorrhage only occurred when she went to stool, and the blood was of a bright colour. Until this hæmorrhage set in she had been a strong healthy woman, possessing a good colour, and she attributed the onset of her illness to the loss of blood. The hæmorrhage continued for at least three months, and rendered her very weak. During this time menstruation was regular, but very scanty. She became gradually weaker, and in March, 1884 (i.e., four months after the date of the first hæmorrhage) vomiting set in. The vomiting continued until her admission into the infirmary, ceasing at intervals, but she had not been free from vomiting for longer than four or five weeks at a stretch. No other symptoms were noticed by the patient except gradually progressive weakness and pallor. Menstruation continued regular, but the flow was very scanty.

The woman presented herself for admission complaining of great weakness and of troublesome vomiting. She appeared to be well developed, with an exceedingly pale, sallow complexion. Her conjunctivæ were quite blanched, and her lips of a peculiar light-blue tint. Her general appearance gave the impression of a person who had suffered from profuse hæmorrhage. Though anæmic, she was not emaciated, being, in fact, well covered and inclining to *embonpoint*. There was not any evidence of cardiac enlargement, except, perhaps, slight dilatation. At the apex of the heart and at the third left costal cartilage there was a faint systolic murmur. The pulse was regular, small, and

Digitized by Google

frequent (120 per minute). There was a well-marked venous murmur at the root of the neck. Respiration was frequent (26 per minute), but easy, and dyspnœa occurred only on exertion. The chest was very tender on percussion, and she complained especially of great tenderness over the sternum. There was not any evidence of disease of the lungs. The blood was pale, the red corpuscles diminished in number, and devoid of their tendency to run together into rouleaux. There were many red corpuscles of an abnormal shape, some of which appeared more or less flask-shaped. The white corpuscles were not markedly increased in number. The area of splenic dulness was increased, and measured in the mid-axillary line four inches and a quarter, and extended forwards to the anterior axillary line. The area of liver dulness was increased, and extended in the right mammary line from the sixth rib to two inches below the costal margin, whilst in the median line its lower edge reached to within one inch and a half of the umbilicus. The surface of the liver felt quite smooth. The urine was of sp. gr. 1015. The reaction was acid, and there was no albumen. There was not any general anasarca, and no swelling of the feet; but there were distinct hæmorrhages beneath the skin over the dorsal surfaces of the feet. The largest hæmorrhages were about the size of half-a-crown, and there were abundant smaller petechiæ. On ophthalmoscopic examination the fundus oculi presented several distinct hæmorrhages, apparently of recent date. There was not any evidence of neuritis, and the edges of the disc were clear and well defined.

On admission she was treated with ten-minim doses of the tincture of the perchloride of iron, but after a few days it was found that the iron set up considerable irritability of the stomach, and for that reason it had to be discontinued. Shortly after admission petechiæ appeared over both knees, and it was elicited from her that six months before her knees had been black, as though badly bruised. The temperature varied, and was usually normal in the morning and 100° in the evening; occasionally, however, it rose to 101° or 102° at night. She vomited at irregular intervals a yellowish fluid, but rarely any quantity of food. Her tongue was clean and her bowels confined. The menstrual flow was scanty, but regular. Ten days after admission she was placed on five-minim doses of liquor arsenicalis, and on the fourth day after taking this a note was made to the effect that she felt and appeared better. The blood, however, on examination still showed a large number of flask-shaped and other irregular corpuscles, and there was a considerable number of red corpuscles of small size, though of normal shape. A pill containing three grains of sulphate of iron was ordered, in addition to the arsenic mixture, but it had to be discontinued owing to the gastric irritation which it set up. The dose of liquor arsenicalis was increased to eight minims, and after a few days fifteen minims of dialysed iron were added. Shortly afterwards a note was made to the effect that she appeared much better, and that there was more colour in her mucous membranes. The dose of liquor arsenicalis was gradually increased to thirteen minims, and the dialysed iron to twenty-five minims, and on these she was kept until February 25th (i.e., two months from the date of her admission). During the interval the woman had changed for the better in a rapid and striking manner. From being bedridden, she was able to get about the ward, and later on the infirmary grounds. She felt much stronger and could walk without fatigue. Her colour deepened, until she was to all appearance normal in this respect; and the temperature, which for the first four weeks of her stay in the infirmary had usually risen in the evening to 100° F., remained at normal both morning and evening during the remaining four or five weeks before her discharge. The splenic dulness diminished, and on her discharge on February 25th, 1885, the lower limit of liver dulness did not exceed the costal margin. On examination of the blood, the red corpuscles were found to have increased in number and to have a tendency to run together into rouleaux; there were, however, a few flask-shaped corpuscles still to be seen, but these were many fewer in number than on admission. On leaving the infirmary she was sent to the Wingfield Convalescent Home for a few weeks, and she left there apparently in perfect health to return to her home in Staffordshire.

In January, 1886 (not quite a year after her discharge), I learned of the death of the patient. She had remained in good health for some time, and then gradually lost colour and strength, and was one morning found dead in her bed. I was not able to obtain any details of the treatment during the patient's second and fatal illness, but I learned from her friends that her symptoms had practically been the same as those which occurred prior to her stay at the Radcliffe Infirmary, and that the medical man in attendance had certified the cause of death as anæmia.

Remarks.—In recording a case of recovery from a disease the essential feature of which is its fatal termination, very strong evidence is required to demonstrate that the clinical observer has not been misled in forming his diagnosis of the disorder. Obviously, if we consider that pernicious anæmia is the fatal goal of simple anæmia, to speak of recovery from such a condition is nothing more than an Irishism. But however close the resemblance between simple and pernicious anæmia, the clinical distinctions between them are, I believe, sufficient to separate them from one another, and to point to the probability of their being distinct diseases. The record of a case possessing all the symptoms of pernicious anæmia in which there was apparently absolute recovery for a period of several months, but in which eventually relapse and death from the same disorder took place, forms a link in the chain of evidence of the existence of pernicious anæmia as a clinical entity, the termination of which, though frequently fatal, is not necessarily so. That this case presented the essential features of pernicious anæmia is, I think, evident. The patient was of middle age, of large frame, and well covered with fat. Her illness had come on gradually, and had been characterised by progressive debility and pallor which had not been accompanied by any wasting, though they had proceeded almost to extremities. She had had hæmorrhages, both subcutaneous and retinal. Her blood presented the characters which have been described in many, though not in all, cases of pernicious anæmia.[1] This derangement of the blood appeared to run a course somewhat parallel to the disease, the blood becoming more normal in its histological characters, with progression of the patient to convalescence, though even when the patient was apparently convalescent the blood still retained a certain degree of its abnormal character. There was enlargement of the liver, rare in cases of simple anæmia, but not uncommon in cases of pernicious anæmia, and this enlargement disappeared with the convalescence of the patient. There was an oscillating temperature, which fell to and remained at normal when the anæmic condition had been removed. There was marked tenderness over the sternum, which abated with convalescence. Finally, there is the fact that after apparent recovery the patient relapsed in the course of a few months, and died from a disease which all the evidence obtainable showed to be pernicious anæmia. The starting-point of the disease in this case was apparently the hæmorrhage which took place from the rectum, but the cause of the hæmorrhage was not apparent. It was not possible to discover any disease of the lower bowel or genito-urinary passages during the patient's stay at the Radcliffe Infirmary, nor did the history show that there were any symptoms of disease of the bowel or genito-urinary passages when the hæmorrhage first occurred. It is possible that the hæmorrhage was due to the altered condition of the blood, and was an early symptom rather than the exciting cause of the disease. It appears from the history of the case that she had subcutaneous hæmorrhages over the knees about six months after the first occurrence of the hæmorrhage from the bowel. The treatment pursued in the case shows the inefficacy of iron as a remedial agent in the advanced stage of pernicious anæmia, though after the patient had progressed towards convalescence iron was given and tolerated by the patient. Dr. Byrom Bramwell has pointed out that in these cases iron is often not only inefficacious but possibly injurious, and certainly in the stage of profound anæmia in this patient I found it to be so. It is to Dr. Byrom Bramwell that the credit of the successful treatment of pernicious anæmia is due, and from his cases the inspiration of the treatment of the present one was drawn. To Dr. Thomas Harris of Manchester, who was house-physician at the Radcliffe Infirmary during the time the patient was an in-patient there, I wish to offer my thanks for the careful notes made by him, and the deep interest he took in the case.

[1] These characters of the blood in pernicious anæmia have been described by Professor Eichhorst of Jena, Professor H. Quincke of Bern, Drs. Byrom Bramwell, Stephen Mackenzie, Padley, Carington, and others. Dr. Pye Smith relates a case in which the blood was apparently unchanged, and I have also had a case under my care which terminated fatally, in which there was not any change in the shape of the red corpuscles.

THE DIAGNOSIS AND TREATMENT OF CHRONIC INTESTINAL OBSTRUCTION.[1]

BY FREDERICK TREVES, F.R.C.S.,
SURGEON TO, AND LECTURER ON ANATOMY AT, THE LONDON HOSPITAL.

FOR diagnostic purposes all cases of chronic obstruction of the bowels may be conveniently classified under the four following conditions, which are arranged in the order of the frequency of their occurrence: 1. Fæcal accumulation 2. Stenosis of the colon (due usually to stricture, and preferably to malignant stricture). 3. Stenosis of the small intestine (due usually to conditions other than stricture). 4. Chronic intussusception. From a pathological standpoint this classification would be of little value. The anatomical causes of chronic obstruction are very numerous and very varied, but they do not produce corresponding clinical variations, and do not lead to distinctions in differential diagnosis. Some of the rarer forms of chronic obstruction, such as those due to partial occlusion of the bowel by an enterolith, and some unusual varieties of volvulus, hardly come under the classification just given. The less common of the four varieties may be first dealt with.

Chronic intussusception.—This term is applied to invaginations that have persisted for more than one month. The anatomical form of the disease that is most apt to become chronic is the ileo-cæcal (60 per cent.); that which is least frequently met with in a chronic condition is the ileo-colic (10 per cent.). No form of intestinal obstruction is more difficult to diagnose, and none gives rise to more ambiguous or more varied symptoms. Out of fifty-five cases collected by Rafinesque only a few were suspected to be examples of intussusception, and no less than twenty-seven were the subjects of an absolutely incorrect diagnosis. The following are the main points in the diagnosis:—1. Age. The great majority of the patients are children or young adults, and in such individuals other forms of chronic obstruction are comparatively uncommon. 2. Mode of onset. The symptoms may commence with a distinct attack of acute or subacute intussusception, and subsequently pass on into a chronic form. Unfortunately in about 60 per cent. of the cases the onset of the disease is insidious, and the earliest symptoms are those probably ascribed to indigestion or slight colic. 3. The invagination tumour. This mass has been met with in about 50 per cent. of the chronic cases, but has been mistaken for a fæcal mass or for a new growth in not a few of the examples. When the tumour has reached the rectum, the diagnosis can seldom remain obscure, but this condition has only been observed in 32 per cent. of the cases. 4. Blood in the motions has been recorded in about half of the instances of the chronic form. As regards other symptoms, there is a colicky pain that is always intermittent, is often absent for a long period, and often slight. The vomiting is not pronounced, is very rarely indeed feculent, and was entirely absent in 50 per cent. of the collected cases. It may be induced in the earlier stages, and made worse in the later stages, by food. The bowels may act with perfect regularity, and may respond readily to an aperient. As a rule they are irregular, with a tendency to diarrhœa, and less often to constipation. Meteorism is absent, the abdominal walls are flaccid, coils of bowel are often clearly seen in movement through the parietes, and the patient wastes and becomes anæmic and cachectic. The symptoms are those of stenosis of the bowel, and unless distinct guidance is afforded by the four cardinal features already detailed, the precise diagnosis of chronic intussusception is scarcely possible.

Stenosis of the small intestine.—In the majority of the cases that come under this heading the bowel is narrowed or bent by peritoneal adhesions. It may be actually formed into a loop by such adhesions, or be compressed by them. In other instances a number of coils may be matted together, or the gut may be narrowed by the shrinking of an inflamed mesentery. Actual stricture of the small intestine is not common. This part of the bowel is the seat of a rare form of multiple simple stricture, the precise nature of which has never been fully explained. Other simple strictures have followed injury, operations for strangulated hernia, and ulceration of a specific character. Primary malignant disease of this part of the bowel is comparatively rare. In the matter of diagnosis sex plays no part and age is of little import. Non-malignant stenoses are most often met with about early middle life, while cancer is most usual after forty. The history of the patient is of considerable importance, especially so far as it concerns previous attacks of peritonitis, a history of pelvic peritonitis, abdominal operations, typhlitis, strangulated hernia, definite injury to the abdomen, mesenteric disease, tuberculosis, dysentery, &c. In some cases the bowel may be partly occluded by a foreign body or a gall-stone, or be narrowed by the pressure of a tumour without its walls, or be stenosed by the growth of a neoplasm within its lumen.

The symptoms produced by a narrowing of the lesser bowel are marked by great variations. The onset is usually gradual, and the progress of the affection is apt to be marked by certain more or less acute attacks. Since the contents of the small intestine are fluid, the bowel may become greatly narrowed before very pronounced symptoms are produced. The narrow stricture is, however, very liable to be abruptly closed by a valvular fold of mucous membrane, by a mass of undigested food, or by kinking of the unevenly distended coil. With the occurrence of such a blocking acute symptoms supervene. Such acute or subacute attacks are apt to appear from time to time. The pain throughout the progress of the disease is distinctly intermittent; long intervals of freedom from suffering, extending at first over many days or even weeks, intervene between the attacks. As the intervals between the paroxysms shorten, the attacks become of longer duration. It is evident in the majority of cases that the pain may be provoked by food, coming on within an hour or so of a meal. The attacks become more and more frequent and severe, and when complete obstruction sets in the pain becomes continuous, but with exacerbations. During the earlier attacks of pain there may be nausea. In the more severe attacks the patient vomits. The vomiting is often provoked by food. It is late to be established, is seldom copious, and rarely feculent, except towards the end of an acute obstructive attack. Constipation is a leading symptom in 10 per cent. of the cases. In 40 per cent. there is constipation alternating with diarrhœa. During the more abiding attacks the constipation becomes absolute. Tenesmus is absent; the abdominal parietes remain flaccid, unless peritonitis be present; and in uncomplicated cases there is no local tenderness. Movements of coils of hypertrophied intestine are visible through the parietes. Sometimes, when the trouble is produced by adhesions, a clump of coils of distended small intestine forms a tympanitic swelling, possibly visible to the eye, at some part of the abdomen. Meteorism is absent, except during acute attacks and with absolute constipation. The patient emaciates and becomes worn out by the continued pain and digestive disturbances.

Stenosis of the colon.—This condition is in the majority of cases produced by stricture, and in nearly 60 per cent. of these cases the stricture is cancerous in character. In the remaining instances the narrowing has followed cicatrisation after ulcer, or has been due to compression of the bowel by severe inflammatory changes outside its walls. In other instances, where no distinct stricture exists, the partial occlusion may be due to the bending of an adherent colon, to some rare forms of volvulus (especially of the cæcum), to obstruction by intestinal growths, or by enteroliths, and by the pressure of a tumour without the bowel. In the commonest condition—that of stricture—the situation of the lesion is especially noteworthy. Out of ninety-nine cases (dealt with in my book on "Intestinal Obstruction," p. 286), the stricture occupied the sigmoid flexure in fifty-eight examples. Eighteen times it was found in the descending colon or splenic flexure, sixteen times in the transverse colon or hepatic flexure, and six times in the ascending colon or cæcum. It will be seen, therefore, that the trouble becomes less common with every inch that it is traversed, proceeding from the commencement of the rectum to the end of the ileum. The general symptoms of stenosis of the colon are very similar to those already described in connexion with the lesser bowel, and the same elements in the history of the patient hold good for the two conditions. The course of the disease is irregular, and is associated with paroxysmal attacks. In the matter of differential diagnosis the following points are to be noted. The pain is intermittent and colicky in character, but it is, on the whole, less severe in cases where the colon is involved. The vomiting

[1] Read at the Medical Society of London, Oct. 24th, 1887.

Digitized by Google

is less marked, and is indeed often absent. In any instance it supervenes at a later period. It is usually less profuse than is the case in stenosis of the lesser bowel. It never becomes stercoraceous, except after many days of absolute constipation. It will be, moreover, especially noted that the symptoms are usually but little affected by food. The bowels are, as a rule, in a condition of constipation, or this condition may alternate with a spurious diarrhœa. The latter symptom is especially common in cancerous stricture low down. In 15 per cent. of the cases of cancer there was a bloody discharge from the anus. Tenesmus is very commonly present, especially in such cases as are associated with diarrhœa. Aperients often give relief in cases of stricture of the small intestine, but are apt to aggravate the symptoms when the colon is involved. Meteorism is usually pronounced, and often very pronounced. Coils of intestine are visible through the wasted parietes, but this feature is never observed at so early a period as is the case with stenosis of the small intestine; it is, moreover, never so marked. The early appearance of visible coils of bowel is very suggestive of obstruction in the lesser intestine. There is seldom any localised tenderness. The outline of the colon above the stricture can be defined, unless the tympanitis is very marked. Towards the later stages of malignant disease a tumour can be made out in some 40 per cent. of the cases.

Fæcal accumulation.—The most important issues in the differential diagnosis rest with the distinctions between stenosis of the colon and fæcal impaction. It is as great a surgical calamity to perform colotomy for the latter condition as it is to persist in the use of enemata and purgatives in cases of cancer of the bowel. Into the causes of chronic constipation, and the anatomical conditions that favour it or result from it, it is impossible to enter. The subjects are mostly adults, and are generally females. The frequent association of the condition with nerve disease, with hysteria, melancholia, and hypochondriasis, cannot be overlooked. It is well also to bear in mind the deformities of the colon that often attend persistent constipation, and that lead to serious errors in connexion with the diagnosis of fæcal tumours. The cases that cause most trouble to the diagnostician are those in which some temporary mechanical occlusion of the bowel (as by kinking) is effected by the fæcal mass, and symptoms of a somewhat acute character supervene upon the chronic phenomena. In the subjects of this affection there is a gradually increasing constipation, which more and more resists the action of aperient medicines. Unlike the circumstances of stenosis, this constipation may reach a quite extreme degree before any vigorous attacks of colic or sickness occur. The patient's appetite declines, his tongue becomes foul, he is liable to eructations and nausea, he is much troubled with flatulence, and soon becomes languid and depressed. One symptom is of considerable moment: the extreme foulness of the breath that is so often met with in fæcal accumulation is almost unknown (perhaps quite unknown in like degree) in the subjects of stricture of the bowel. As the case advances the abdomen becomes distended. It is rare for coils of hypertrophied bowel to be visible through the parietes, and if such a symptom does appear, it will appear late. As the obstruction becomes more complete the abdomen may become painful. It is well also to note that there is often tenderness on handling about fæcal tumours. The abdominal pain assumes a paroxysmal character, but it is not apt to reach the degree common in stenosis. If vomiting occurs, it appears late, is very scanty, infrequent, and not feculent, unless there has been absolute obstruction for a considerable period. Especially is it to be noted that the symptoms of pain and sickness appear late, and seldom manifest themselves until there is evidence of a distended bowel. One of the most important features in the diagnosis is the fæcal tumour, into the protean characters of which it is not possible to enter. Enemata as means of diagnosis are practically useless. In many cases they do little more than demonstrate the capacity of the rectal pouch. Still less useful is the long tube. This instrument is not only a delusion, it is a snare; and its valuelessness as a diagnostic agent can be well demonstrated on the post-mortem table. In one instance in which the long tube was passed, its point could be felt just above the umbilicus. A medical friend, disregarding the anatomical measurements of the bowel, wished me to believe the instrument had reached the centre of the transverse colon. At the necropsy an impermeable stricture was found at the lower end of the descending colon. The tube had only reached the summit of the sigmoid loop, which can, in a large proportion of cases, be made to reach the umbilicus, and even (in a few instances) the liver. The accumulated fæcal masses may press upon the lumbar or sacral nerves, or upon the iliac or pelvic veins, and so produce a variety of symptoms. When the probability of a tumour can be excluded, these phenomena are of the greatest value.

Upon the matter of *treatment* I can only deal in slight outline. I have discussed the treatment of intussusception in a previous paper, read before the Medical Society.

In dealing with *stenoses of the small intestine*, the most important measure undoubtedly is diet. The patient should be restricted to a diet of the most simple and the most easily digested foods. A primary object is to reduce the solid matter in the bowel to a minimum. The connexion between the acute obstructive attacks and errors in diet is often easily to be traced. The patient should take plenty of liquids, to help to maintain the fluidity of the intestinal contents. Cod-liver oil may also be given with little or no intermission, unless it provokes nausea. Aperients should be avoided when possible. The action of the bowels can be maintained by massage of the abdomen and the occasional use of enemata. The injections should be copious. The acute attacks of pain, with constipation, vomiting, and distension of the abdomen, are met by rest, opium, starvation, and the washing out of the stomach. The latter measure may give more relief than the narcotic. In the case of a lady with stenosis of the lesser bowel following pelvic peritonitis, relief—which appears likely to be maintained—has followed the treatment by diet, &c. Previously to this treatment she had had three attacks of acute obstruction in twelve months, and during the third attack the vomiting had become feculent. If the case becomes steadily worse (as will probably occur with pure stricture) and all milder measures fail, there is no alternative but laparotomy. In this operation adherent or compressed bowel may be set free, and the procedure prove to be of a simple character. This can only occur in the minority of the cases. In examples of stricture the involved segment has been excised, and the divided ends united by Lembert's suture, with perfect success. In some cases of adhesion also a like resection may be called for. One point, however, is imperative. If the operation is performed during the occurrence of an obstructive attack, the diseased segment may be excised, but in no case should an attempt be made to at once unite the divided ends. An artificial anus should be established, and the opening so made closed by a subsequent operation. Such a procedure amounts to little more than an enterotomy, and the success of this operation, as viewed from its comparative mortality, has been clearly demonstrated. Of the many sutures designed for use upon the intestine, the best and simplest is the suture of Lembert.

Into the treatment of *fæcal accumulation* it is scarcely possible to enter. The question is one mainly for the physician. One small point that has, perhaps, not received quite the attention it deserves may be alluded to in passing. The need of a proper proportion of fluid in the intestinal canal must be recognised. In some instances, where very hard, dry, fæcal masses are passed, the constipation would appear to be in large measure due to the lack of sufficient fluid in the bowel. The patient, perhaps, drinks very little liquid. One now and then meets with a lady who is satisfied with one glass of sherry at dinner. Another patient perspires inordinately. A third is a neurotic subject who passes so large a quantity of urine that his condition approaches that of diabetes insipidus. In each instance it would seem that too little fluid remains in the bowel, and the fæces are not of such consistence as to be readily passed along the intestinal canal. If this defect be remedied, a very substantial improvement will probably follow. When actual fæcal impaction occurs, the diet should be limited, and any pain checked by belladonna or opium. As soon as the abdomen ceases to be tender, massage should be commenced and carried out systematically for twenty minutes twice a day. After the rubbing and kneading of the abdomen an enema should be administered. The injection should be copious; it should be given always in the knee and shoulder position, and the best apparatus for the purpose is undoubtedly Lund's instrument. Massage and enemata are the main therapeutic agents. When the bowel begins to clear itself aperients may be employed. For this purpose calomel appears to act admirably when given in doses of from 5 gr. to 10 gr.

Digitized by Google

It should be followed by some saline aperient, such as the mistura alba of the hospitals. In the hands of French surgeons extraordinary and excellent results have attended the use of metallic mercury administered by the mouth. The dose varies from 50 grm. to 300 grm. I have tried this metal in two instances, but without the least benefit, and at the same time without ill effect. It is claimed that the mercury, which is passed per anum in a very finely divided condition, acts mechanically. In some of the reported cases over 1000 grm. have been given in successive doses.

In the treatment of *stenoses of the colon* the same general measures are adopted as have been described in speaking of stenoses of the small intestine. Dieting is important, but at the same time its beneficial effects are not so self-evident. The bowels should be kept well open. For this purpose some of the natural aperient waters should be employed and daily enemata made use of. Frequent examination should be made to detect any fæcal accumulation within the colon. In these cases massage of the abdomen is certainly attended by some advantage. As the case becomes worse aperients cease to be admissible, and in the majority of instances the question of operation sooner or later arises. A difficulty now appears as to the proper method of procedure. Inasmuch as the most frequent cause of chronic obstruction is stricture, the usual operation performed for the relief of the patient is colotomy. There may be little difficulty in diagnosing the case as stricture, and still less in indicating its seat. Under such circumstances a colotomy is performed in one or other loin. It is allowed by most surgeons that lumbar colotomy has decided advantages over the inguinal operation. The peritoneal cavity is not opened, the artificial anus is not inconveniently placed, and statistics show that the mortality after the operation is lower. It is claimed that the inguinal opening gives an opportunity for exploration in cases of doubtful diagnosis. This exploration, so far as the colon is concerned, must of necessity be so limited that its value may well be questioned.

Coloctomy is a procedure that has not found much favour with English surgeons. It is difficult, and has been attended by a high death-rate. It is justifiable if the actual stricture is encountered at the colotomy wound. In such a circumstance the removal of an inch or so of the bowel may not add to the gravity of the operation, and if performed early for malignant growth may modify the further progress of the disease. The resection of portions of the ascending or descending colon through an anterior wound is fraught with formidable difficulties. Through such a wound the cæcum or a segment of the transverse colon can be dealt with, but to minimise the risks of the operation a temporary artificial anus should be made. The closure of this by a subsequent plastic operation may not be difficult, but such attempts at promoting union are very unsuccessful in connexion with artificial anus in the loin. Colectomy performed through the ordinary lumbar incision will probably result, under the best conditions, in a permanent fæcal fistula. The absence of a peritoneal covering to the bowel in this situation renders a successful suturing of the gut most improbable.

The main point, however, in the operative treatment of chronic obstruction lies in the question whether colotomy is really the best measure for a particular case. In obscure forms of the condition a surgeon may well hesitate before he commits himself to so decided an operation. He may open the ascending colon in the loin, and find subsequently that the obstruction was at the ileo-cæcal valve. Or a left lumbar colotomy may be performed, and the case prove to be one of fæcal impaction. In other instances the obstruction may prove to have been due to the bending of the bowel by adhesions, or to chronic volvulus, or to enterolith, or to other conditions that may possibly have been relieved by laparotomy, and without the formation of an artificial anus. In all these case of doubt, and they must necessarily be of frequent occurrence, I would strongly advise an exploratory incision in the median line. If the examination proves the case to be one demanding colotomy, that operation may be either carried out at once—and possibly through the median line,—or the peritoneal wound may be closed and a lumbar colotomy performed at a later period. I might quote the following cases as illustrating these two alternatives.

I saw with Dr. Henry Stokes of Highbury, in April last, a lady about fifty years of age who presented the symptoms of chronic intestinal obstruction. There was nothing in her past history that threw any light upon the case. The symptoms had only existed fourteen days. At this time she had been nursing her husband, and her bowels had become irregular. She was seized with slight colic, and took a dose of castor oil. This produced what was considered to be a natural motion, but greatly increased the colic. She at once consulted Dr. Stokes. Previously to this attack she had never had colic, and her bowels had been very regular, with a disposition to looseness rather than to constipation. The patient was kept in bed, and was carefully dieted. The pain was quieted by opium and belladonna, and frequent enemata were administered. When I saw the patient there had been absolute constipation for fourteen days. The abdomen was swollen, and it was evident that there was an obstruction low down in the colon. The cæcum was greatly distended; no hypertrophied coils of intestine were visible through the parietes. The tongue was not much coated; the breath had never been offensive. There had been but little vomiting. The patient was rapidly losing strength. The opium was discontinued for a while; forcible enemata were given in the knee and shoulder position; massage of the abdomen was carried out. The patient became worse under this treatment, and the abdomen much more distended. The case was not sufficiently clear to lead me to commit the patient at once to the serious trouble of an artificial anus. The symptoms were of so recent a date and of such a character as not to accord with the usual phenomena of stricture of the bowel. At the same time, I have met with cases of cancer of the colon where the first evidences took the form of an almost acute obstruction. In one of these the sudden closure of the already narrowed bowel led to symptoms that could scarcely be diagnosed from acute volvulus of the sigmoid flexure. Under these circumstances I opened the abdomen in the middle line, the constipation having been absolute for about eighteen days. I was ably assisted by Dr. Fraser Stokes. A typical epitheliomatous stricture was discovered at the termination of the descending colon. The sigmoid flexure was empty. I should have wished to have closed the abdomen, and performed later on a left lumbar colotomy. The state of the colon, however, prevented this. This gut was extremely distended; the cæcum was enormous, and in several places its peritoneal coat had given way. Perforation of the bowel would have been a matter of not many hours. I therefore brought the cæcum to the parietal wound, to the edges of which I attached it by a row of sutures, none of which, however, opened the lumen of the bowel. I brought all the most damaged part of the gut out of the wound. When the parietal wound had been closed as far as necessary, I punctured the cæcum through one of the rents, and allowed an immense volume of gas to escape. No solid matter was seen. I then clamped the hole in the bowel, and dressed the wound with iodoform. The patient was greatly relieved by the tapping of the bowel. She never vomited after the operation. On the fifth day, the exposed bowel, having become firmly adherent all round to the abdominal wound, was opened by Dr. Stokes. A large quantity of fæcal matter escaped. The patient made a rapid and uninterrupted recovery. When seen six months after the operation, I could detect no mass in the seat of the stricture; the patient looked in excellent health, and had gained flesh. The artificial anus gave less trouble than I should have imagined. Nothing had passed the rectum since the operation.

The second case that serves to illustrate the value of an exploratory incision was that of a married woman, aged twenty-seven, who was admitted into the London Hospital under my care on Oct. 27th, 1886. On admission, there had been absolute constipation for five weeks; the abdomen was greatly distended; the vomiting, however, was slight, and not frequent. From her history the patient would appear to have had some peritoneal troubles after one of her confinements. She had always had difficulty with her bowels, and the present trouble had come on very gradually and with little pain. She appeared to be too young for cancer. Nothing could be felt per rectum that threw light upon the case. She had never had dysentery, and there were no grounds for suspecting a simple stricture. The case might possibly have been one of narrowing or kinking of the bowel by peritoneal adhesions, and to have condemned a young woman of twenty-seven to colotomy for that condition would have been a calamity. I therefore opened the abdomen in the median line, and soon found a carcinomatous

Digitized by Google

stricture at the commencement of the sigmoid flexure. I could find no adhesions. As the colon was still in good condition I closed the wound. The operation did not last many minutes. In eight days the median wound was practically healed. I now performed a left lumbar colotomy, opening the bowel at once. Both wounds did very well. The patient recovered rapidly, and was enabled five weeks after the colotomy to resume her household duties.

I have selected these two cases because the trouble was identical in both, but the symptoms induced were as unlike as the limits of the conception of chronic obstruction would permit. One patient was advanced in life; the other was only twenty-seven years of age. In one the symptoms came on somewhat abruptly, in the other gradually. In the more chronic case the distension of the bowel was less than in the case of shorter duration.

Wimpole-street, W.

PARALYSIS OF THE ABDUCTORS OF THE VOCAL BANDS.

By GORDON HOLMES, M.D.,

PHYSICIAN TO THE MUNICIPAL THROAT AND EAR INFIRMARY, LONDON; CONSULTING PHYSICIAN TO THE SHEFFIELD EAR AND THROAT HOSPITAL.

(*Concluded from page 804.*)

Pathological Anatomy.—Like all other paralyses, that under consideration may be either central or peripheral, myopathic[1] or neuropathic. When the disease is myopathic the information to be obtained from necropsies is in general sufficiently clear and easily attainable; but in neuropathic cases, owing to the extremely long course of the vagus and the complexity of its connexions, the pathological anatomist has often an almost insuperable task before him when trying to trace out the obscure lesions which may constitute the esoteric origin of the malady.[2] In all such researches, therefore, the physiology of laryngeal innervation must be well borne in mind. The two following facts are the leading ones in this region of inquiry:[3] (*a*) the spinal accessory nerve supplies motor filaments for all the muscles of the larynx (*including* the crico-thyroid) *except* the posterior crico-arytenoids; (*b*) the pneumogastric nerve, before meeting the spinal accessory, contains the motor supply for the posterior crico-arytenoid muscles, and for them only. These, be it remarked, are muscles of organic life, and almost if not wholly removed from the sphere of volition.[4]

Most writers on this paralysis, notably Semon[5] and Rosenbach[6], argue from clinical evidence that in all lesions of the general nerve trunks supplying the larynx the fibres going to the abductor muscles are first affected. Now all neurologists subscribe to the fact that in central or peripheral nerve lesions the extensor muscles are most liable to become paralysed. Hence, if we place the posterior crico-arytenoid muscles in the category of extensors, it will appear that their innervation exhibits the same vulnerability seen in other muscles having analogous functions. At the same time, however, even if this assumption be granted, it carries us but a little way towards explaining the phenomenon, and merely shifts the burden from the shoulders of the laryngologist to those of the general neurologist. But whether the muscles in question can really be set down as extensors is extremely doubtful. The motion of the crico-arytenoid joint is chiefly one of rotation, with the point of rest about midway between the extremes of movement. Thus it seems to depend merely on the mental attitude of the individual whether abduction or adduction be regarded as flexion or extension. Thus, for example, one person may recognise in irregular masses of cloud &c. striking resemblances to various concrete forms which another entirely fails to perceive. In order to settle this matter, further evidence of a more positive kind will have to be discovered, and I can only suggest to observers having facilities for such researches, that something in the domain of comparative anatomy or embryology might be adduced to identify adduction and abduction of the vocal bands with flexion and extension as exhibited in the limbs. In any case, we can accept the general facts without endeavouring to draw a parallel, which can never be complete, owing to the abductors not being within the category of ordinary voluntary muscles.

Franklin Hooper,[7] being extremely sceptical as to the alleged preter-vulnerability of the abductor fibres, has made some valuable experiments on dogs with a view to settling the question. In one instance the recurrent laryngeal nerve was gradually destroyed by chromic acid, but as long as a fibre of the nerve held together electric stimulation produced abduction in the etherised animal. In other cases inflammation was kept up for a week or more by a thread passed through the substance of the recurrent laryngeal nerves. Though some considerable irregularities in the action of the muscles were thereby produced, no decided paralysis of any one set was obtained. On the whole, however, the lesion seemed to influence chiefly the adductors.[8] With a view to refute Hooper, Semon and Horsley[9] have also carried out a careful series of experiments, which show very clearly that the abductor muscles lose their electric excitability long before the adductors. As they remark, "the abductors *die* sooner than the adductors." On the whole, it appears probable that the abductors, as muscles of organic life, and differing somewhat in molecular constitution,[10] are less able to bear any interference with their innervation than the adductors. To the practical mind this will seem a distinction without a difference. Still the preter-vulnerability of their nerve fibres is not satisfactorily established, and it is understood that Hooper is again at work in the endeavour to bring the whole question to a scientific conclusion. From a clinical point of view I think it unlikely that the ground occupied by Semon, Rosenbach, and others will be disturbed.

A further important point for consideration is whether many of these cases are not really due to a *primary* contraction of the adductors. Some writers, especially Krause,[11] are keeping this question well in view during their investigations. Whilst it seems possible that irritation by pressure on the recurrents may impel the adductors into a state of fixed contraction, some experiments by Donaldson jun.,[12] of Baltimore, accidentally suggest a negative to the proposition. This observer, in trying to verify Hooper's observations, found that slight stimulation of the recurrents caused abduction, and strong stimulation adduction, of the vocal bands. Hence, it may be inferred that the mild irritation of pressure by a tumour would provoke continued contraction of the abductors.

With respect to the structural alterations occurring in this disease, a considerable number of necropsies have been obtained in which both neuropathic and myopathic lesions have been discovered. As a rule, in those instances where alterations of the brain or nerves have been noticed the substance of the muscles has also been materially disturbed, but in several cases myopathic conditions alone have been brought to light. Thus, in a case examined by von Pentzoldt[13]

---

[1] Myopathic cases may be defined as those in which no distinct nerve-lesion can be discovered or surmised. Some authors who have interested themselves in the neurological relations of this paralysis go so far as to deny the existence of myopathic instances, believing that a neuropathy is always concomitant, however obscure. This is clearly an exaggerated view, and an application of the "nothing like leather" principle. Myopathies are too well recognised in pathology for these muscles to be allowed a logical exemption from disease *per se*.

[2] It must not be forgotten to mention that H. Krause of Berlin believes he has discovered a cortical centre for the larynx in the *gyrus præfrontalis*. "Ueber die Beziehungen der Grosshirnrinde zu Kehlkopf und Rachen" (Zeitschr. f. Anat. u. Physiol, 1884).

[3] It is all the more necessary to dwell on the actual scheme of laryngeal innervation, as it appears to be overlooked by almost all writers on laryngology. Even so recent and comprehensive a writer as Ziemssen (Cyclopædia of the Practice of Medicine, vol. vii., 1875, p. 914) is imbued with the erroneous views of Bischoff and others that the spinal accessory nerve alone furnishes the motor filaments contained in the vagus.

[4] Ordinarily, irritation of the recurrent nerves produces constriction of the glottis: but Franklin Hooper of Harvard (New York Medical Journal, July 4th, 1885) has brought out the interesting fact that when volition is completely abolished it has the opposite effect, and strong abduction of the vocal bands occurs, even when the nerves are completely severed. His experiments have been made on dogs under the influence of ether. They have since been confirmed by several other investigators.

[7] Loc. cit.

[8] Previously to Hooper, Krause (Virchow's Archiv, Bd. xcviii., 1884) had made some experiments in dogs by subjecting the recurrent nerve to continued irritation for several days, after which he professed to find degeneration of the abductor muscles. His paper, however, is too inconclusive to be regarded as proving anything.

Digitized by Google

the roots of the vagi and spinal accessory nerves were found to be thin and grey, whilst there was grey discolouration of the olivary bodies and adjacent parts, accompanied by marked sclerosis. The pneumogastric and recurrent nerves were preternaturally thin and grey in their whole course, and there was fatty degeneration of the neurilemma. At the same time the posterior crico-arytenoid muscles were of a pale-brownish colour, showing indistinct transverse striation of their fibres, as well as infiltration with fat and yellow pigment. Syphilitic cicatrices existed in the throat of this patient, a female aged sixty-one. In most cases the paralysis, whether unilateral or bilateral, results from the pressure of some tumour on the vagi or recurrent nerves in or near the thoracic cavity. Thus we often find it associated with aneurysm of the arch of the aorta, enlarged bronchial glands, malignant intra-thoracic growths, tubercle in the lung apex, especially the right,[14] bronchocele, &c. In such instances the nerve at the place of lesion may be found thinned to such an extent that it resembles a band of tissue paper, or so embedded in connective tissue that the remains of nerve structure are with difficulty identified. In other cases, whilst the muscles have undergone marked atrophy and fatty degeneration, no alteration in the brain or nerves have been discoverable.

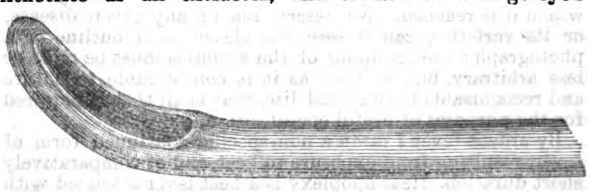
Diagnosis.—The laryngoscopist can scarcely make an error in diagnosing this malady. Ankylosis of the crico-arytenoid joint (a much rarer affection), in which the vocal bands cannot be fully separated, may simulate it; but concomitant circumstances will be almost certain to render a mistake unlikely.[15] Spasm of the glottis, although it causes dyspnœa referred to the larynx by the patient, can scarcely mislead the most unpractised observer, as the narrowing of the glottis is restricted to occasional fits, mostly occurring in the evening. Thus at ordinary times the larynx presents a perfectly normal appearance. Spasm also is almost confined to children, whilst paralysis of the abductors has only once or twice been met with before adult age. Moreover, it must be noted that many persons adopt a very constrained position of the muscles of the throat during laryngoscopic examination, especially on first occasions. Such patients often fancy they must hold their breath whilst the mirror is in the mouth, and sometimes they even close the larynx completely by approximating the ventricular folds to avoid breathing. By custom and a little instruction from the practitioner these difficulties are soon surmounted.

Prognosis.—In most instances of the bilateral form it is a matter of considerable complexity to arrive at a decided prognosis, but the future of a case can seldom be pronounced favourable unless the malady is manifestly due to a recent cold, and there is a clear tendency to rapid amelioration. When the paralysis is caused by an aneurysm, intra-thoracic growth, or other tumour, the general prognosis will usually depend on the nature and curability of the primary disease. The same observation applies to lesions of the nervine centres. But even if the primary malady should be cured, the posterior crico-arytenoid muscles cannot be expected to regain their functions if their innervation has been long enough disturbed for atrophy or fatty degeneration to any extent to have taken place. Again, the question will lie for consideration as to whether tracheotomy may or may not be required. This point is determined mainly by the state of the adductor muscles. Should they be affected by paresis or paralysis of any grade, as mostly occurs in neuropathic cases where the abductor paralysis is merely the most pronounced phenomenon of a general laryngeal paralysis, the stenosis of the glottis is unlikely to attain its maximum, and operative interference may be avoided. In myopathic instances, however, clearly ascertained, we must expect a steadily progressive constriction of the glottis, and tracheotomy must not be deferred too long, as in such a case a mere cold in the throat may so quickly aggravate the symptoms as to bring about almost suddenly a fatal result, unless the windpipe can be opened immediately. As regards the unilateral paralysis, it need only be said that it is of little or no clinical importance with respect to the larynx.

Treatment.—When the paralysis results from lesions extraneous to the larynx, the treatment proper to such disease is chiefly demanded. Thus, we may have to treat aneurysm, goitre, syphilis, or other brain affections, &c. At the same time, if the laryngeal symptoms are urgent, tracheotomy must be performed without delay. It is useless to postpone this operation, even when the primary malady shows a marked advance towards cure; because if, as often happens, the nerve has become involved in a growth of connective tissue, its functions are not in any case likely to return. Nor under any circumstances is a well-marked case likely to become ameliorated so rapidly that tracheotomy, when called for by a high grade of dyspnœa, can be escaped. When the cause has been removed, the best chance of restoring the muscular powers lies, of course, in the application of galvanism. In order to stimulate the posterior crico-arytenoid muscles, the laryngeal electrode must be passed down the back of the pharynx and insinuated into the entrance of the œsophagus. It can then be drawn upwards and outwards on each side from the mesian line over the surface of the muscle, as it lies in the hollow prepared for it on the back of the cricoid cartilage. The process may be repeated several times at each sitting, and the passes should be increased in frequency as the case progresses. Daily applications, or on alternate days, should be persevered in for some weeks, even when the results are negative. For the purpose of applying galvanism in this situation, the round knob which is the regular termination of the laryngeal electrode is not very convenient, and had better be replaced by a somewhat flattened and wedge-shaped extremity. In examples of abductor paralysis of an undoubted rheumatic or simple inflammatory character, warm inhalations, such as the *vapor benzoini* or *vapor pini sylvestris*, will best promote a speedy cure.

Finsbury-square, E.C.

[14] According to Mandl (Gazette des Hôpitaux, No. 135, 1862), out of fifty-two patients affected with tubercle of the right apex fifty were hoarse, whilst of thirty-two persons whose left apex was involved only one had any vocal derangement. Mackenzie (Diseases of the Throat, 1880, p. 446), however, conceives that the vocal troubles in phthisis are mostly the result of general muscular paresis from debility. Although this statement is undoubtedly true as to some cases of aphonia, almost confined to young females, it cannot in the least explain away Mandl's statistics, which point plainly to a unilateral affection of the laryngeal muscles.



[15] Ziemssen (op. cit.) gives a case, which was not satisfactorily diagnosed until the necropsy; but at no time was it really thought to be paralysis of the abductors.

ON

SUCTION IN THE REMOVAL OF FOREIGN BODIES FROM THE BLADDER.

By REGINALD HARRISON, F.R.C.S.,
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.

I DO not think the value of this method of removing foreign bodies from the bladder is fully appreciated. Formerly, for the extraction of pieces of bougie, slate pencil, and bodies of this shape, I was in the habit of using the lithotrite as an extractor, and I have published several cases where this instrument proved to be efficient when the foreign substance had not been largely encrusted with phosphates. The chief difficulty connected with the use of the lithotrite under these circumstances is the fact that the foreign body is invariably seized at right angles with its long axis, and that it is necessary to get hold of an end before extraction along the urethra can be effected without damage to the parts. More recently I have discarded the lithotrite as an extractor, and trusted to a large-eyed

evacuating catheter, such as I use for lithotrity, and a rubber wash-bottle connected with it, by means of which I can fill and empty the bladder with a stream of water of considerable force. When we consider that most foreign bodies introduced into the bladder are of an elongated nature before they become nuclei for stony concretions, this method of removing them at once commends itself to us. The evacuating catheters I employ have a large eye, as shown in the annexed illustration. If a rubber bottle is attached to them and a stream of water is forced into and out of the bladder, it will be found, as a rule, that the end

Digitized by Google

of the foreign body is sucked into the catheter, and in this way may be withdrawn.

One of my recent cases was a curious one, and was seen in consultation with Dr. Robert Roberts. A middle-aged healthy man, a month previously, passed a piece of bacon rind about two inches in length up his urethra, which disappeared. Not feeling satisfied with this strange exploit, he introduced, a week afterwards, up the same canal, a stiff pig's bristle about five inches in length, which also disappeared. Ten days before I saw him he felt a severe pricking sensation, and at once confessed his indiscretions to his medical adviser. When we saw him in consultation I passed a soft instrument down his urethra, and distinctly felt something in the prostatic urethra, which I pushed backwards into the bladder. As I felt so doubtful as to the man's statement, I employed a small lithotrite, with which I felt something I could not hold. I then passed a large-eyed evacuating catheter into the bladder, and attached a powerful rubber syringe to it, such as I use for the removal of stone fragments after lithotrity. After a few movements of the syringe I felt that I had engaged something in the eye of the catheter, and on withdrawing the latter, the bristle, beautifully coated with phosphates, came with it. Of the bacon rind I neither felt nor heard anything more. These manœuvres were quite easily carried out on my consulting-room sofa without an anæsthetic. Some weeks previously I had removed a piece of gum-elastic bougie (No. 6), three inches in length, in the same way. To commence with, I felt, as the water current was being ejected, the bougie struck against the eye of the catheter with its long axis, and was therefore not caught. I distended the bladder with another syringeful of water (four ounces), when at once the end of the bougie became impacted in the eye of the evacuating catheter, and was withdrawn like the bristle. The additional amount of water permitted the bougie to rotate in the bladder. Still more recently, by the same process, I dislodged a renal calculus which I believe was impacted in the orifice of one of the ureters, where for some weeks it had caused much irritation.

Liverpool.

HEATSTROKE.[1]

BY JOHN ANDERSON, M.D., C.I.E., M.R.C.P.,
BRIGADE SURGEON, RETIRED.

A GREAT deal has been written on the subject of heatstroke; still it has occurred to me that a brief account of my experience in India in this respect might not be altogether void of interest.

If we exclude heat exhaustion, which is simply the result of exertion and fatigue in hot weather, where the sufferer falls down with a freely perspiring and cold skin, and where the phenomena of sun or heat stroke, which I am about to describe, do not ensue; then, I think, the following division will embrace the various forms of the disease: 1st, Ardent Fever; 2nd, Heat Apoplexy; 3rd, Sunstroke. Such a classification seems to me more fully in accordance with the deviation from the normal temperature of the blood; the effect varying not only in relation to the height of temperature reached, but also in relation to the rapidity with which it is reached. No description of any given disease, or its varieties, can possess the clearness of outline of a photograph: the grouping of the varieties must be more or less arbitrary, but so long as it is conformable to nature and recognisable in practical life, that is all that is required for the purposes of useful classification.

By ardent fever I mean a non-specific continued form of fever, resulting from exposure to heat, and of comparatively short duration. Heat apoplexy is a heat fever attended with high temperature, contracted pupils, cyanosis, loss of consciousness, and a marked tendency to death by asphyxia. It more commonly results from the indirect effects of solar heat, or radiated heat, and usually occurs at night, in dwellings or in crowded tents. Sunstroke is a form of heat fever with a very high temperature, contracted pupils, and rapid loss of consciousness, and it is frequently attended with convulsions indicative of perverted action and exhaustion of the nerve centres. Both here and in heat apoplexy there is marked cardiac debility and embarrassment, probably largely due to a paresis of the sympathetic heart centres. In brief, it will be seen that all three of the foregoing are pathologically allied; they are, as it were, so many beads of different sizes and colours united on one and the same thread.

In ardent fever we have commonly portal congestion and increased metabolism of the liver, *plus* the effect of heat on the nervous system. In heat apoplexy we have a poisoned state of the blood resulting from vitiated atmosphere, arrested secretions, with possibly the addition of alcohol, forming in combination the dominating factor; and heat, not direct solar but radiated heat, as the subordinate but determining factor. In sunstroke, we have the direct and dominating factor of solar heat, acting on the cortices and meninges of the brain and spinal cord, *plus*, it may be, a toxæmia as a subordinate predisponent factor.

I would here refer for a moment to the two main sources of animal heat—viz., the muscles, which are the chief source; and the glandular organs, which stand next in order of importance. The muscles of an adult man form nearly half of the whole body weight, and contain about one quarter of his blood. From this, says Foster, "it may be inferred that a large part of the metabolism of the body is carried on in the muscles." Whenever a muscle contracts, heat is given out; and wherever metabolism is, there heat is generated. It is not difficult, therefore, to understand what a seriously predisposing cause to this disease over-exertion is, over and above the nervous exhaustion resulting from fatigue. Of the glandular organs the liver is by far the most important. It contains about a quarter of the whole blood of the body, and we know what extensive metabolism takes place in that organ. It is consequently clear that congestion of the portal system, induced by intemperance in food and drink, is also a powerful predisponent.

Then we have the regulation of the body heat. Of these, the three principal regulators are the skin, the lungs, and nervous systems. The skin is the most powerful; it regulates by means of conduction, radiation, and evaporation of perspiration from its surface. It is obvious that conduction and radiation can reduce the heat of the body but very feebly when the surrounding media are as hot as, or hotter than, the body itself; and when the air is moist and still, as well as hot, evaporation from the surface is reduced to a minimum. In the severe forms of the disease, more particularly in heat apoplexy, we have stertor, and so engorged a condition of the lungs that, on section post mortem, the blood drips freely from the cut surfaces. Hence we may assume that the heat-regulating sources of these organs are seriously impaired. Foster, in his work on Physiology, shows how the vaso-motor mechanism influences the regulation of the body heat. He tells us that a vaso-motor action, which by constricting the cutaneous vascular areas, or by dilating the splanchnic vascular areas, causes a smaller blood flow through the skin and a larger one through the abdominal viscera, will tend to increase the heat of the body. But this observer, while admitting that the influence of the nervous mechanism in animal heat, not only in maintaining the normal temperature, but also in affecting the variations of temperature in disease, can hardly be exaggerated, adds that much requires to be learnt before its exact value can be confidently spoken of. I think, however, I have shown how the sources of heat are increased and the outlets blocked. From this we must have rising body temperature with heatstroke as the result, unless the supply be diminished or the outlets opened.

And now I come to the treatment, and it is chiefly on account of a point that I wish to emphasise in this part of my subject that I have ventured to bring this subject forward.

Prophylactic measures, though perhaps obvious, cannot be passed by unnoticed. People who live, and soldiers who serve, in hot climates cannot get rid of heat; but they can do much to modify it by living in well-ventilated rooms, with a suitable proportion of cubic space and superficial area for each occupant. They can make the still air move by means of fans or punkahs. They can be temperate both in eating and in drinking; and more particularly they can abstain from alcohol altogether, or take it only sparingly and well diluted with water. Alcohol has a powerful deleterious influence, because (1) it increases portal congestion, and (2) it has, whilst in the circulation, a great attraction for water. They can clothe in garments that are light

[1] Read in the Military and Naval Section of the International Medical Congress, held at Washington.

Digitized by Google

both in colour and in weight, and loose enough to admit of the freest respiratory movement. Dr. Arnold Hiller, of the German army, in a lecture he very recently delivered to the officers of his corps, laid great stress on the importance of this point; indeed, he regards great heat alone as a subordinate factor to the detention and accumulation of heat brought about by heavy clothing. He also relates some experiments showing the great value of perspiration and its increased effects when assisted by wind. When troops are marching in hot weather, the march should be made at night, or sufficiently early to be completed by 7 A.M. Urgent military necessity is the only good reason for neglecting this precaution. The ranks should be as open as possible, and care should be taken that the men's water bottles are filled before starting. Cold tea flavoured with lime-juice is an excellent beverage for the purpose. Tea and coffee are excellent respiratory excitants, and free from the evil influences of alcohol. The marches should not be too long, and food should be taken before starting and at halting places as safeguards against fatigue.

In cases of simple ardent fever, the initial step in the treatment is to relieve the congested portal system by an aperient, and none is more suitable than a dose of calomel (from two to four grains), followed by such a saline as sulphate of magnesia. Cold sponging of the body or the wet pack lowers the temperature, refreshes the patient, and frequently induces sleep. Quinine, in doses of two or three grains, is indicated, and in my experience has proved efficacious. The bromides of potassium or ammonium are useful. In the Punjab and North-West Provinces of India I have often seen over 20 per cent. of the strength of recently arrived regiments in hospital in the months of April, May, and June from this cause. Here I may incidentally remark that at Peshawur we have two forms of fever differentiated from each other by the seasons of their accession or prevalence. In April and May it is an ardent fever, short in duration and continuous in type, over which quinine exerts no specific influence; in brief, it is the ardent fever of which I am speaking. But in October and November we have a fever of an altogether different type—viz., a malarial fever varying in degree from a simple ague to its most pernicious form, resembling cholera, in which quinine, arsenic, and change of air are alone of any avail.

In the graver forms of heatstroke much more active measures are urgently called for. My practice has been to strip the patient instantly; to lay him on an inclined plane by raising the head of his bed from ten to fifteen inches from the ground; to place him, if possible, in a current of air, and, failing that, to make attendants circulate the air around him by fans or hand punkahs. He should be douched freely, but not suddenly, by pouring cold water in good volume over the head, chest, and abdomen; and the bowels should be quickly cleared by an enema. None of these measures should be omitted. But what I am especially anxious to bring to your notice is the beneficial results obtained by the hypodermic use of quinine in these cases. As far as I am able to ascertain, this is not the general practice of English physicans, whatever it may be with those of this country. Sir Joseph Fayrer, in his able article in Quain's Dictionary of Medicine, incidentally remarks that "this method of treatment has been supposed to give good results by its influence on the vaso-motor nerves and retarding tissue change." And Dr. Roberts Bartholow, in his work on the Practice of Medicine, says: "The subcutaneous use of quinine may also be practised to reduce heat." I venture to think, however, that in quinine so employed we have a remedy of much efficacy in such cases—at least it has proved so in my experience in many instances; and I believe its more general use would be attended by a much lower mortality than that usually recorded in this disease. I have seen patients in a state of coma from heatstroke so far recover in from ten to fifteen minutes after the subcutaneous injection of quinine as to be able to protrude the tongue when desired to do so, and to show by signs or speech that they understood a question put to them. I have a clear recollection of having one morning, when in cholera camp at Mian Mir, without a tree to shelter our tents from the fierce heat of a Punjab sun in July, by the subcutaneous use of quinine, with a fatal result only in one instance, treated fourteen cases of heatstroke. All these cases were of such severity that the patients were insensible. The dose I use for injection is from two to four grains, and this may be repeated at such intervals as may be indicated by the condition of the patient. I have administered a second dose in half an hour after the first, and a third in two, three, or four hours after the second. When we reflect how narrow is the line between life and death in these cases of hyperpyrexia, and remember that with a body heat of even 107° F. there is still time to save life, but that at 111·2° death ensues, it is everything to possess an agent which will control the degree of temperature in a few minutes. I claim for the subcutaneous use of quinine in the treatment of heat-stroke this property.

There are certain precautions that must be observed in this method of administering quinine. 1. The solution must be perfectly clear; it must be filtered if necessary. 2. The salt used must be one that is perfectly soluble in distilled water without the addition of any acid. Such a salt is the quininæ hydrobromas acida. This is a very soluble form; it dissolves 1-6 of water, it is richer in the alkaloid than the sulphate, and it is quite unirritating. Both of these precautions are essential in the hypodermic use of quinine, because some local irritation may follow the injection. I have heard of two cases of tetanus that were alleged to have been caused by the operation. In my own practice no such misadventure ever occurred, and I have used quinine subcutaneously many hundreds of times; for before I became acquainted with the advantages to be gained by treating heatstroke after this method, I had frequent recourse to it in the treatment of obstinate malarial fevers, when quartered in such malarial districts as the Valley of Peshawur, in the north of the Punjab. The addition of morphia to the quinine solution has been proposed as a safeguard, but I never found its use necessary, and of it I have no experience. How quinine acts in the way I have described I cannot tell, but that it has a special effect on the nervous system, particularly the cardiac ganglia and the vaso-motor nerves, seems highly probable, from the rapidity with which the effect follows the injection. I am aware that some eminent authorities—Professor Binz for example—hold that quinine exercises some specific influence on the blood-corpuscles; still, I believe the explanation is rather to be found in its effect on the nervous system.

Since the date of my service in India, several new antipyretics have been introduced; and I understand that antipyrin, for example, has been used hypodermically in America in the treatment of heatstroke. I know that in the British army both antipyrin and antifebrin have been employed in the treatment of ardent fever with very beneficial results, and their use in sunstroke will consequently be indicated.

PENETRATING WOUND OF ABDOMEN WITH PROTRUSION OF INTESTINE; ABSENCE OF SHOCK.

BY J. W. GRANGE, M.B., C.M.

A. N——, aged twenty, a ploughman in robust health, while walking through a field, was attacked by a bull, knocked down, and gored in the abdomen. The bull's attention was then directed to a couple of dogs, the only help at hand, and the man escaped over a hedge. He says that when he rose up his trousers were torn and bloody, and he saw his bowels hanging out, forming a large mass, which he caught in his hands. Supporting them in this way, he walked home, a distance of a quarter of a mile, and up-hill, before he could get any assistance.

As the man lived far out in the country, it was two hours after the injury had been inflicted before I saw him. He was then lying in bed, and did not present any symptom of shock. His face was of a good colour, his pulse strong and steady, and there was nothing in his appearance to indicate that he had met with such a serious injury. On opening his trousers a large mass of intestine lay over the right side of the abdomen, in volume about as much as one could carry in two hands, consisting of about four feet of small intestine and mesentery. The bowel was dull and congested from constriction, but otherwise uninjured. The wound, completely hidden by the overlying bowel, was situated in the right iliac region. It was rectangular in shape, and about four inches long. The opening in the peritoneum, however, would barely admit one finger. After cleaning the bowel from sand and dirt, reduction was tried, but unsuccessfully, as any attempts to replace the bowel sent it into

Digitized by Google

the areolar tissue outside the peritoneum. The difficulties of the situation were also increased by a sudden and violent act of vomiting, which covered the protruded bowel with vomited matter; this was evidently caused by the attempt at reduction. The intestine was again cleansed and the wound in the peritoneum enlarged, after which reduction was easily effected, and the wound closed by sutures. A simple cold-water dressing was applied, from necessity, not from choice, and opium freely prescribed. With the exception of a small collection of pus which formed in the abdominal wall, the patient made a good recovery.

This case appears to be worth recording from the fact that a man with such an injury was so slightly affected by shock as to be able to walk a considerable distance without assistance, and also on account of the recovery without the employment of antiseptics. The second and subsequent dressings were of wood-wool, but their application was too late to keep the wound aseptic.

Cumnock, N.B.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

INFANTILE PARALYSIS LIMITED TO THE BULBAR NUCLEI, WITH PERMANENT PARALYSIS OF HALF THE FACE AND TONGUE.

BY W. PASTEUR, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE NORTH EASTERN HOSPITAL FOR CHILDREN, HACKNEY ROAD.

R. D——, aged two years and seven months, was sent to me in November, 1886, by Dr. Scoresby-Jackson of Walthamstow for an opinion. The mother gave the following account of her child's illness. His health had been excellent up to the end of July, 1886, when he had a sharp attack of "fever," with diarrhœa and sickness. On the second or third day of this attack she noticed some twitching of the corners of the mouth, and carpo-pedal contractions, but there was no "fit." On the following morning the face was drawn to one side, the child was unable to close his right eye, his talk was unintelligible, and when given milk to drink, he made no effort to swallow, but allowed it to run out from the right corner of the mouth. For two or three days life was almost despaired of. On the fourth day there was some return of the power of swallowing, which was completely restored in about a month. There was at no period of the illness any cough or regurgitation after taking liquid food. In six weeks from the date of onset speech was completely recovered, with the exception of a slight thickness of utterance, which still persists. There were never any signs of paralysis of the arms or legs. I may add there was no history of traumatism, diphtheria, or ear disease.

When I saw the child for the first time on Nov. 22nd, his condition was as follows: A strongly built, robust-looking boy, thoroughly spoilt, and quite intractable. There is complete paralysis of all the branches of the right facial nerve, without any naked-eye evidence of muscular wasting. (Electrical examination impossible on account of the child's temper.) The tongue when protruded deviates markedly to the right; its right half seems to be a trifle thinner than the left, but is not wrinkled on the surface. The muscles of the limbs are everywhere well developed. Swallowing is performed normally, and hearing is unaffected. The movements of the eyes are normal; the pupils are equal and active. There has never been strabismus.

At the end of January, 1887, the child could close the right eye rather more completely than when first seen; except for this his condition was unchanged. During repose the paralysis was hardly perceptible, but became very obvious when the child spoke or cried. Dr. Scoresby-Jackson has since written to me that the right side of the face is a little wasted.

Remarks.—The mode of onset and clinical features of this case are so unequivocal that I have little hesitation in recording it as one of infantile paralysis. The remarkable distribution and limitation of the paralysis are quite new to me, and must be very uncommon. I can find no reference to similar cases in any of the treatises and monographs I have consulted on the subject, and several eminent neurologists to whom I related the case had never met with one exactly like it. As regards the original extent of the paralysis I cannot speak with any certainty. It is evident, from a consideration of the early symptoms, that several of the bulbar nuclei were temporarily thrown out of gear; and as the child was kept several weeks in bed, it is just possible that some slight temporary paralysis of the limbs was overlooked. The very small amount of muscular wasting is remarkable, seeing that the paralysis had already lasted fully six months when the patient was last seen.

Queen-street, Mayfair.

THE VALUE OF COCAINE AS A LOCAL ANÆSTHETIC.

BY G. MICHELMORE, M.R.C.S., L.S.A.

So much has been written in THE LANCET lately on the value of cocaine as a local anæsthetic that the following cases in which it was employed may be of some interest. A 20 per cent. solution of the hydrochlorate of cocaine was used in all the cases.

William L—— was admitted into the Tiverton Infirmary on March 22nd suffering from a severe injury to the right eye, which necessitated extirpation. Twenty minims of the solution were dropped into the eye at intervals during the operation, which was painless.

Ann H——, admitted on April 5th for the removal of a fatty tumour on the left shoulder. The surface of the tumour was painted over with the solution, and fifteen minims injected around its base. No pain was felt during the operation.

Richard G——, admitted on July 19th for the removal of the right eye. Cocaine was used in a precisely similar manner as in the first-mentioned case, and with the same results.

Sarah S——, admitted for the removal of an epitheliomatous growth on the bridge of the nose and adherent to the nasal bones beneath. The growth was painted over with the solution, and fifteen minims injected around the base; it was then freely excised, and the parts beneath scraped and swabbed over with a strong solution of chloride of zinc, the patient showing no signs of pain.

Emma V—— required the removal of a finger at the terminal phalangeal joint on account of a bad crush. The finger was painted over with the solution, and ten minims deeply injected. No pain was felt during operation.

The Infirmary, Tiverton.

A CASE OF PEMPHIGUS RECURRING AFTER FOUR CONSECUTIVE LABOURS.

BY OCTAVIUS CROFT, L.R.C.P.L., M.R.C.S.

PEMPHIGUS occurring during pregnancy is mentioned as a rare occurrence. Barnes[1] refers to a case which lasted three months and ended in complete recovery after delivery. In another case[2] it recurred during several successive pregnancies. In all, however, it seems to have disappeared with the termination of the pregnancy. The following case therefore is of some interest from the fact that the eruption on each occasion developed soon after delivery, lasted several weeks, and was entirely absent during pregnancy. It occurred in the outside Maternity Charity of the Leeds General Infirmary.

Mrs. A——, aged thirty-seven. Has had twelve children and one miscarriage. Her husband is healthy, and there is no history of syphilis in husband or wife. Beyond some debility resulting from her numerous confinements she usually enjoys good health. On Nov. 12th, 1886, after a natural and easy labour lasting about six hours, she was delivered of a healthy living child. All went on well for a few days—so well, indeed, that she herself thought she would escape another attack. On the fourth day, however, she felt ill, and in the course of a few hours the eruption broke out. A few blebs appeared first on one arm, which were of various sizes, and contained clear fluid. They subsequently developed in other situations, such as the dorsum of the foot, the back of the neck, and the face. The mucous membranes were not affected. The constitutional disturbance was

[1] System of Obstetrics. [2] Quain's Dictionary of Medicine.

Digitized by Google

slight: there were anorexia, restlessness, and general feeling of malaise, but no rise of temperature. General tonic treatment was prescribed, together with full doses of arsenic. The blebs were pricked and dressed with boracic acid and vaseline. Improvement soon took place, but blebs occasionally appeared, and the disease did not entirely disappear until five or six weeks after the confinement. Following the patient's last three previous confinements, she has had exactly similar attacks; they have usually commenced about the fourth day after delivery, and have lasted for several weeks. The first attack lasted ten weeks; the second also about ten weeks; the third lasted fifteen weeks, and was the most severe of all; the fourth and last was the mildest, and accompanied with less general disturbance than the others.

Leeds.

AN UNUSUAL CASE OF MUCOUS CYST.

By F. W GIBBON, L.R.C.P.E., L.S.A., &c.

ON Sept. 9th I attended Mrs. G—— in confinement of a fine healthy female child. The following morning the nurse informed me that the infant had not passed urine, and drew my attention to a "tumour" filling up the vaginal cavity, which she attributed as the cause, especially as she said it came down very much when the child cried. On examining the child, I found a large cystic tumour, about the size of a pigeon's egg, which appeared full of pus; and on manipulating it and pressing it to one side the bladder relieved itself. I was puzzled, first, as to its situation, coming from a space between the clitoris and the meatus urinarius; and, secondly, as to its size and consistence, as it could not have arisen in fourteen hours, the time after delivery. However, with a bistoury I slit it up, and the contents were discharged (pure pus), the tumour disappeared, and four days afterwards the walls of the cyst came away. The child has had no other symptoms.

LONDON HOSPITAL.

A CASE OF GASTROSTOMY FOR ŒSOPHAGEAL OBSTRUCTION WITH SUCCESSFUL RESULT.

(Under the care of Mr. M'CARTHY.)

THE following account of a case of successful gastrostomy—successful not only so far as the operation itself was concerned, but also in the relief afforded by it—is interesting; and we hope to be able to publish further details when the case has terminated. Already five months have elapsed, during which the patient has enjoyed comparative comfort, being saved from the dread of impending starvation, and able to make such good use of the opening as to gain flesh and strength. The operation was one specially indicated by the condition of the stricture, which was impassable to even the smallest bougies.

A wharf labourer, aged forty-seven, was admitted on the medical side of the London Hospital, under the care of Dr. Sansom, on April 6th, 1887, for inability to swallow. He said that he had had trouble in swallowing for about ten weeks, but that for the last few days solid food seemed to lodge a little way down his throat, and was then vomited; and that of liquids only a small quantity passed into his stomach, and the greater part was thrown up soon after it had been swallowed. Notwithstanding his assertion that he had lost flesh considerably, he was by no means emaciated, and weighed 137 lb. Examination of the throat, internally and externally, disclosed nothing. His heart was normal, and there was no evidence of thoracic aneurysm. Hepatic dulness extended for two inches below the ribs, and there was increased resistance to pressure in the right half of the epigastrium. All attempts to introduce bougies failed. Even the smallest-sized instrument was arrested about two inches from the commencement of the œsophagus. Nothing could be ascertained from his family and personal history to elucidate his condition. He stated that he had never had syphilis, and there was no indication of that disease. He was occasionally subject to epileptic fits. For three weeks he was fed with nutrient enemata, as any food taken by the mouth was vomited, and many attempts were made ineffectually to pass bougies.

As the man had then lost six pounds in weight, and was becoming very weak, Mr. M'Carthy was requested to accept the case for operation. Accordingly on April 27th the operation was performed. The patient having been anæsthetised, an incision two inches long was made parallel and about three-quarters of an inch internally to the left costal cartilages, the middle of the incision corresponding to the convexity of the ninth cartilage. The skin and fascia having been divided, the skin was drawn inwards so as to expose the sheath of the left rectus abdominis muscle. This was then divided vertically for two inches, and, the muscular fibres having been separated with the handle of the scalpel, the posterior layer of the sheath and the peritoneum were opened vertically for about one inch and a half. Through this opening Mr. M'Carthy introduced one finger and explored the right half of the epigastrium. A hard nodular tumour, about the size of a pullet's egg, could be felt in the upper surface of the liver, but it was quite out of sight. The stomach was then attached to the anterior wall of the abdomen in the usual manner by two rows of sutures round the opening: one of carbolised silk, about three-quarters of an inch from the margin of the opening; and the other of silkworm gut, at the margin itself. The part was then dusted with iodoform and covered with a wood-wool pad.

For four days the patient was fed solely with nutrient enemata. On the fifth day Mr. M'Carthy made a small incision in the stomach wall, and through this, when it had been dilated with a pair of dressing forceps, a soft rubber tube was introduced, and about two teaspoonfuls of egg-and-brandy mixture were injected. The patient at once complained of severe pain in the left shoulder and supraclavicular region, which gradually abated after two or three hours. When the house-surgeon, Mr. Walker, repeated the injection at night, similar pain was felt, but after some days the patient ceased to complain of it. During the ensuing forty-eight hours the patient had five epileptic fits, and then became for some days furiously delirious. It was subsequently ascertained that he had been at one time in confinement for insanity. When the delirium subsided, the patient became very apathetic and his conjunctivæ were deeply jaundiced. The stomach was contracted and irritable, and the patient had a troublesome cough, so that for some time very little of what was injected was retained in the stomach, and nutrient enemata were still requisite. Gradually the stomach became more tolerant of food, and the patient improved so much that by the end of May he was able to leave his bed. He was then weighed, and had lost from the time of the operation 22 lb., weighing only 108 lb. The obstruction in the œsophagus had also diminished, for he was now able to swallow milk, arrowroot, and custard pudding easily. This improvement in swallowing was very temporary, and at present (Oct. 19th) he can only swallow a small quantity of fluid, and this is sometimes immediately vomited. From the end of May his progress has been uninterruptedly good, and his gain in weight considerable, his present weight being 156 lb. His general condition is very good, and his only trouble is some excoriation of the skin round the gastric opening, from leakage of fluid from the stomach.

WORCESTER GENERAL INFIRMARY.

CASE OF PERFORATION OF AN ULCER OF SMALL INTESTINE DUE TO A FALL, ASSOCIATED WITH FRACTURE OF FOUR RIBS BY DIRECT VIOLENCE.

(Under the care of Mr. HYDE.)

THE notes of the case were taken by Mr. T. P. Gostling.

Joseph S——, aged sixty-six, was admitted on Sept. 20th, 1887, at 7.30 A.M. He stated that between 11 and 12 P.M. on Sept. 19th he was walking home from Worcester, a distance of three miles, in the road, and stepped on one side to avoid a carriage. As soon as this had passed he stepped into the road again, and turned half round to look after it, when he

Digitized by Google

was immediately struck in the side and knocked down by the pole of a carriage which was following close behind the first. He got up and walked, with assistance, to his house, a distance of three-quarters of a mile. Up to the accident he had been quite well.

On admission, seven hours and a half after the accident, he complained only of pain on breathing in the mid-axillary region of the right chest, and of vomiting brownish fluid. He was quite conscious. The extremities were cold, pulse scarcely perceptible, and temperature subnormal. There was slight bruising of the front of the right shin, side of the right thigh, and of the scrotum. In the line of the right anterior axillary fold, over the third, fourth, fifth, and sixth ribs, there was a slightly marked bruise two inches in diameter. No emphysema was observed in the region of this bruise, but crepitus was extremely well marked. There was no cough. There was no bruising of the abdomen, which was flat, very rigid, and scarcely moved in respiration. Two ounces of urine were drawn off from the bladder; it was quite clear, and contained no blood. Vomiting was almost constantly present, everything given by the mouth being returned at once; the vomit being of a dark yellowish-brown colour, and giving the bile pigment reaction. Attempts to give food and stimulants by the rectum failed, as the injections were at once returned. There was a slight incised wound on the left eyebrow. At about 11 A.M. (twelve hours after the accident) the patient complained of slight pain in the right inguinal region, which was relieved by hot fomentations; but about 8 P.M. this returned, and became severe and general all over the abdomen, and the patient died half an hour afterwards.

Necropsy, fourteen hours after death—Rigor mortis well marked. On the surface of the body there were some slight bruises, as described above. On reflecting the soft parts from the chest, blood was found to be extravasated into the tissues which cover the third, fourth, fifth, and sixth ribs in the line of the right anterior axillary fold, and these ribs were each fractured in two places—i.e., about two inches from the attachment of the cartilages and just in front of their angles. On opening the chest, no adhesions were found on the left side, but there were a few old adhesions between the front of the right lung and the chest wall. Both pleural cavities contained about five ounces each of blood-stained serum, and the bases of both lungs were of a dark-red colour. On opening the abdomen, no extravasation of blood was found in the abdominal wall. The intestines were found to have lost their shiny appearance, and the vessels in them and in the great omentum were everywhere very much congested, especially on the right side, where there was a little fresh lymph between the coils of intestine. The abdominal cavity contained about fifteen ounces of thick yellow fluid, which had a fæcal odour. Before removing the intestines they were examined, and a small oval opening about one-third of an inch across was found in the ileum about six feet above the caput cœcum coli. On removing the intestines and slitting them up, it was found that the edges of the opening were slightly raised, rounded, and smooth, and they did not present the least appearance of having been torn. No other ulcers were found. The liver was fatty, and there were old adhesions between it and the abdominal wall.

Note by Mr. HYDE.—The chief interest of this case is found in the existence of a single small ulcer of the intestine, the base of which had become sufficiently thin to be ruptured by a severe fall, and the very slight symptoms caused by the peritonitis present.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

The Condition and Management of the Intestine after Abdominal Section.

THE first ordinary meeting of the winter session of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Mr. J. D. MALCOLM contributed a paper on the Condition and Management of the Intestine after Abdominal Section, considered in the light of Physiological Facts; of which paper the following is an abstract. The author directs attention to the origin and distribution of the nervous supply of the intestine, and to its influences on the production of peristalsis, of intestinal secretions, and of intestinal gases. He concludes that all the functions of the intestine are under the control of automatic nervous plexuses in its walls, and that these are closely associated with the central nervous systems, but are also affected by all stimulations acting directly upon them. It is shown that stimulation of the motor plexus produces increase of its activity, followed by exhaustion and paralysis of its function in proportion to the severity of the stimulus; but that the influence of the nervous system on the production of secretions and of gases in the intestine is not so well understood. It is suggested that the chemical action of one intestinal secretion on another may be a source of the excessive flatulence of certain diseases, which has not been satisfactorily accounted for, but which "seems to be in some measure connected with defective or deranged innervation." (The above portion of the paper was illustrated by numerous and full quotations.) The author proceeds to show that in every abdominal section the intestine is abnormally stimulated, and the result is compared to that which causes the "after-constipation" of purgatives. Evidence is adduced of paralysis of the bowel after these operations, passing into paresis, and gradually recovering at the end of from four to six days; and it is observed that the excessive development of intestinal gases which occurs at this time is "connected with defective or deranged innervation." The importance of the escape of these gases is remarked on, and the causes of their retention are detailed and considered. Intestinal paresis is shown to be an important factor in the production of obstruction of the bowels in these cases, and a possible sole cause of death with symptoms of obstruction. (Cases were quoted, related, and explained.) The symptoms of obstruction of the bowels after abdominal section and the mode of death from this cause are examined, and the post-mortem appearances are referred to. It is shown that excessive or irritating discharges retained in the peritoneal cavity quickly produce symptoms of obstruction and of peritonitis. The author assumes that a local peritonitis must occur whenever the peritoneum is divided and does not heal by first intention, but he believes that general peritonitis—in the absence of septic influences—is one of the rarest of the primary complications of these operations. Septic peritonitis is described as a combination of peritonitis, blood-poisoning, and paralytic obstruction of the bowels, the intestinal symptoms being considered secondary to the paralysis of the gut induced by the peritonitis. The condition of the mental power and of the urine, and the post-mortem appearances, are contrasted with those in aseptic conditions. In the management of these cases the necessity of having the bowels cleared of all accumulations before operation is insisted on, and the greatest care is advocated in avoiding all unnecessary exposure and manipulation of parts during operation. The importance of securing immunity from infection of any kind is considered paramount; but the stimulating and chilling effects of carbolic acid and of Lister's spray producer are mentioned as dangers. After operation, the necessity for intestinal rest is urged, and the use of opium commended. Treatment of vomiting and abdominal distension by the early administration of purgatives is advised, unless the evidence of peritonitis is distinct; and the explanation is offered that purgatives act beneficially simply by stimulating the exhausted bowel to perform its functions. It is advised that irritation from discharges in the peritoneal cavity should be prevented by means of Keith's method of drainage, and that general or extensive peritonitis, when it does occur, should be treated by drainage, rest, and suitable nourishment administered by the bowel. Treatment of peritonitis by purgatives is condemned as dangerous, irrational, and inefficacious.—Mr. ALBAN DORAN did not think that flatulence was necessarily due to the operative interference, for there were many causes of flatulence, and the mere lying in bed of individuals who were unaccustomed to this mode of life might cause flatulence. Nightmare might occur after ovariotomy, and might be mistaken by the nurse for more serious disturbance; it was largely due to the supine position often adopted by the patient after operation. He considered that opium might be useful, but often tended to produce a feeling of depression accompanied with dyspepsia. Further, the formation of scybala should not be favoured, and opium undoubtedly predisposed to this formation.—Mr. KNOWSLEY THORNTON was in general agreement with the opinions expressed in the paper, which dealt with a most important subject. The flaccid condition of the intestine after the operation was of pretty general occurrence, and the causes were, he believed, as Mr. Malcolm had indicated.

Digitized by Google

This flatulence was rather beneficial than otherwise, because the local collection of fluid was prevented. He had strongly been impressed with the power the peritoneum had in dealing with fluid in contact with it, preventing the fluid from becoming septic; the peritoneum could absorb fluid which had not become septic, and without harm resulting. He did not think the condition of the intestines before operation was sufficiently considered by some; the state of the intestine might vary in different parts. Patients often died on the fifth day, and at the end of the thirty-sixth hour; and at one time Mr. Thornton thought that these deaths were due to different kinds of septicæmia, but Mr. Malcolm's suggestions were worthy of careful consideration. A coil of intestine lying in a pool of fluid might become sodden and paralysed, and become a source of septicæmia from the intestinal contents soaking into the collection of aseptic fluid and rendering it septic. The difficulty of differential diagnosis was often extreme between simple obstruction from fæcal accumulation and from incipient peritonitis. A dose of white mixture might save life or might do great harm, but the diagnosis of when to use it was very often extremely difficult to ascertain. He could never recall a single case in which the secondary use of a drainage tube had saved life. The quiet period after ovariotomy, in which the intestines were devoid of air, was a strong argument in favour of Mr. Malcolm's view. He did not concur in Mr. Doran's view of nightmare being necessarily due to the mere supine position.—Mr. CLEMENT LUCAS was inclined to support the views of Mr. Malcolm on the causation of paralysis of the intestines. Such paralysis was observed after lumbar nephrectomy. He had seen cases of death from simple over-distension of the intestine. In one case of hernia in an old man who adopted the supine position, it was found that an oblique position, with the shoulders and head raised, was most convenient for allowing of the escape of gas from the mouth. Obstruction of the bowels, due to tubercular peritonitis, might arise suddenly and cause death. Exposure and injury of the bowels as well as peritonitis were the chief causes of distension of the bowels.—Mr. MERREDITH thought benefit could sometimes be obtained in cases of flatulence by a raising of the lower part of the patient, so as to favour the escape of flatus by the anus. In place of opium he had found injections of twenty drops of tincture of belladonna to be useful in reducing the flatulence. He had found opium to be exceedingly useful in many cases.—Mr. WARRINGTON HAWARD said that many years ago Mr. Travers had drawn a graphic picture of the bad influence of over-stimulation of the nervous system in cases of abdominal operation. The employment of purgatives before operation, by exhausting the nervous energy, might prove of great harm later. He could not help thinking that opium must prove serviceable by giving the bowel sufficient rest to enable it to recover its tone.—Mr. A. E. BARKER asked for an explanation of the occurrence of distension and collapse of bowel—two such opposite conditions. — Mr. MALCOLM, in reply, said that his paper only dealt with the more severe and complicated cases, not with ordinary ones of ovariotomy. The causes of flatulence, he thought, were much wanting in elucidation.

MEDICAL SOCIETY OF LONDON.

The Diagnosis and Treatment of Chronic Intestinal Obstruction.—Notes on Methylal.

A MEETING of this Society was held on Monday, Oct. 24th, Dr. J. Hughlings Jackson, F.R.S., President, in the chair.

Mr. FREDERIC TREVES read a paper on the Diagnosis and Treatment of Chronic Intestinal Obstruction, a report of which will be found in another part of our present issue.—Mr. DAVIES-COLLEY had found a difficulty in diagnosing peritonitis and typhlitis from intestinal obstruction.—Mr. BOWREMAN JESSETT considered the long tube as a diagnostic instrument fallacious; for in cancerous strictures of the sigmoid flexure with a long meso-colon it was not difficult to displace the gut to the right side of the abdomen. He preferred inguinal colotomy, as being not more dangerous, and decidedly more comfortable to the patient.—Mr. BERNARD PITTS had seen a case of chronic obstruction in the small intestine caused by a band. In his experience stricture of the cæcum and cæcal region was much more frequent than Mr. Treves's statistics seemed to show. He referred to a case in which he twice successfully performed colectomy; the first time for cancerous stricture, the second for a recurrence in the glands of the meso-colon. He thought that with lumbar colotomy a better artificial anus was obtained.—Dr. DE HAVILLAND HALL advocated the treatment of stricture of the small intestine by rectal suppositories of beef peptonoids every four hours, the rectum being washed out once daily with tepid water.—Mr. ALLINGHAM jun. had found that with inguinal colotomy patients had sufficient sphincter power, and could keep themselves much cleaner. In some cases of fæcal accumulation he had seen much benefit follow forcible dilatation of the anal sphincter.—Mr. TREVES, in reply, said that the points he relied on in the diagnosis of peritonitis from obstruction were the presence of ascites, the continuous character of the pain, the posture of the patient, the tenderness of the abdomen, the constant and "meaningless" vomiting, the early distension of the abdomen, and the complete absence of visible coils of bowel. He still used the spray on superstitious grounds. The peritoneal cavity was washed out with many quarts of water, and the dressing consisted of a solitary piece of sponge dusted with iodoform, which was kept in place from five to eight days; in addition he washed out the stomach, which markedly improved the condition of the pulse and prevented vomiting. He preferred lumbar colotomy, as being a less fatal operation and more convenient for the patient. In cases of constipation due to painful sphincter, he imagined dilatation might be useful.

Dr. B. W. RICHARDSON read some notes on Methylal. He said that the fluid called methylal, a specimen of which he placed before the Society, was one of the series of chemical bodies which, like nitrite of amyl, methylene dichloride, methyl iodide, the ethylates of sodium and potassium, and some others, was introduced into therapeutics in his reports to the British Association for the Advancement of Science between the years 1863 and 1872. Methylal, which is made by distilling pure methylic alcohol with sulphuric acid and manganese peroxide, has recently been brought forward as if it were an entirely new addition to medicine, whereas it was a substance of twenty years' standing in English medicine, and had been placed by him before the Society, with an experimental demonstration of its anæsthetic effects upon a pigeon, during the year of his (the speaker's) presidency. Methylal was described in the author's first report upon it, in 1868, as a clear fluid of sweet ethereal odour, as of chemical composition $C_3H_8O_2$, of specific gravity 0·855, vapour density 38 (taking hydrogen as unity), boiling point 108° F. or 42° C., and as having the physiological property of producing anæsthesia by inhalation of its vapour, the sleep being gentle and slow, with perfect insensibility. It was remarked also that the substance produced no vomiting or other stomachic disturbance. It was found to render blood of dark colour, and slightly to suspend coagulation, but it did not dissolve the corpuscles, and, left in contact with blood for thirty-five days, it yielded no crystals. Dr. Richardson next related a research, reported in 1869, in which it was shown that methylal could be administered by the mouth with water, or could be introduced into the body by hypodermic injection, under both of which methods its hypnotic properties were produced. He followed this up with an account of the phenomena attendant on a fatal administration of methylal in lower warm-blooded animals, showing that the heart, extremely relaxed, ceased to act before cessation of the breathing in consequence of its distension with blood: it ceased, that is to say, in diastole, a characteristic mode of cessation under all anæsthetics that are of the pure hydro-carbon type. The lungs were collapsed, but of pale-red colour, and the brain, liver, and kidneys were intensely congested. The blood was found fluid, and in one case remained fluid in the vessels for half an hour after death. It was remarked in these researches that in the rabbit the vessels of the ear were intensely congested during the anæsthesia, and that the temperature fell 1° F. through each stage of the narcotism. The author next stated that three years ago, suspecting that the methylal he had hitherto used contained some foreign substance, he asked Mr. John Williams, the well-known operative chemist, to make him a perfectly pure specimen. Mr. Williams did so, but the cost of redistilling to free the fluid altogether of acetone was very great—6s. an ounce for the pure substance. As the author had anticipated, the action of perfectly pure methylal, though similar to that of the common variety in the market, was very much more prolonged and difficult. In 1884-5 he tested pure methylal at Mr. Mavor's Veterinary Hospital in

Digitized by Google

Park-street, for the production of anæsthesia on dogs about to undergo a surgical operation. The results were unsatisfactory. They (Mr. F. Mavor and himself) failed to produce sufficient anæsthesia for operation, after half an hour's inhalation of an air saturated with the vapour. A short intoxication alone was produced, with profuse salivation and some coryza, followed by rapid and complete recovery. Trials by the hypodermic method had the same effect. Into one animal thirty-two grammes were injected subcutaneously, with production of drowsiness, but without anæsthesia. The stomach again remained unaffected. Dr. Richardson next brought forward his experience of methylal as a therapeutical agent. He had very often prescribed it in doses of from one to four drachms, combining it for the sake of the flavour with orange flower spirit, and adding water (proportions: methylal, one drachm; syrup of orange, half a drachm; water, half an ounce). Administered in this way by the stomach, it possessed hypnotic and antispasmodic properties of considérable value, and its grand service will lie in the treatment by it of spasmodic and painful affections, such as asthma, angina pectoris, colic, and tetanus. Its chief value will probably consist in its use as a menstruum for other substances of the same therapeutical action. The author has used it in this way with nitrite of amyl in the treatment of angina pectoris, and he exhibited a very ingenious inhaler, invented by Mr. Charles Smith of Brighton, in which a mixture of methylal and the nitrite (ten parts nitrite, ninety parts methylal) was being employed. The vapour given off by this mixture is extremely pleasant. But it is more than pleasant; by the combination the action of the nitrite is less sudden and much more prolonged, a very considerable advantage. Another combination was shown of methylal with pure anhydrous ethylic ether. As the boiling points of these two fluids, their vapour densities and their specific weights are closely allied, and as both contain the same elements, Dr. Richardson thinks they will form an excellent anæsthetic compound, the solubility of their vapours in the blood being considerably greater than when ether is used alone. He had only had one experience of this mixture, but that was extremely favourable. The paper concluded with the following summary:—1. Methylal is hypnotic and antispasmodic. 2. Its action lies between methylic alcohol and ethylic ether; it may be looked on as a volatile alcohol, and resembles closely pure methylic alcohol in action. 3. It can be adminstered by inhalation as vapour, by hypodermic injection, and by the mouth in aqueous solution. 4. It reduces arterial tension, and by local action excites glandular activity. 5. The sleep it induces is not profound unless the dose be excessive; it is quickly eliminated, and leaves no serious effects; it causes no vomiting or stomachic disturbance. 6. A fatal dose by inhalation kills by complete relaxation of the muscular fibres of the heart, leaving the heart distended with blood and the vascular organs intensely congested. 7. It combines with ether, alcohol, amyl nitrite, and many other remedial agents with which it acts in concert, and equalises their action by reason of its own solubility. 8. Its tendency is to maintain the fluidity of the blood, and it may therefore be of service in combination with ammonia. 9. It promises to yield a safe and effective anæsthetic mixture in combination with ether. 10. It reduces the animal temperature, but not to the same degree as common alcohol. 11. Used as an anodyne, it passes out of the body without producing organic injury, when not often repeated. 12. But, like all bodies of its class, it must be given in increasing quantities in order to keep up its effects, and it would soon yield evil as well as good by its habitual use in the community at large.

OPHTHALMOLOGICAL SOCIETY.

Hereditary Optic Atrophy.

AN ordinary meeting of this Society was held on the 20th inst., Mr. E. Nettleship, F.R.C.S., Vice-President in the chair.

Dr. S. HERBERT HABERSHON read a paper on Hereditary Optic Atrophy. After briefly referring to the early cases of hereditary amblyopia reported in the pre-ophthalmoscopic period, he gave a short summary of Leber's description of the disease founded upon the cases of fifty-five individuals in fourteen families. The disease was confined almost exclusively to the male members of the family, appearing commonly at or about the age of puberty. It consisted of a central amblyopia, coming on usually with suddenness, and simultaneously, or nearly so, in the two eyes. The failure of sight progressed up to a certain point a few months or so after the attack commenced, and there remained stationary, without improvement and without manifest deterioration. The fields of vision were never contracted at the periphery, but presented in most cases a central scotoma, more or less absolute. Colour sense was abolished or much diminished. There were no symptoms of any importance. Headache frequently accompanied the attack, but was never severe. Occasional functional disorders of the nervous system were present, and subjective light and colour phenomena were seen. Sight was never completely lost, and was very rarely improved by treatment. The ophthalmoscope revealed the appearances at an early period of a partial papillitis, while in those cases which were observed later there were pallor and incomplete atrophy of the disc. Some cases more recently reported were then briefly described, together with some unpublished cases, one of his own and six of Mr. Nettleship's, which the latter had allowed him to make use of. These added seventy-five individuals to the original number of Leber. Statistics gathered from them showed that the disease was roughly grouped about two periods of life, puberty and that of the decline of the sexual functions. The great majority occurred at the age of puberty, for of sixty-five in whom the age of onset was known, nearly fifty occurred between the ages of thirteen and twenty-three inclusive. In answer to the question "What other diseases of the optic nervous system bear the stamp of heredity?" he compared the group of retinitis pigmentosa and allied affections, contrasting them with Leber's disease. He decided that consanguinity had very little to do with the disease under discussion. All hereditary diseases represented in the histories of the patients or their families were then mentioned, and the question of how far they were prone to produce amblyopia was entered into. Amongst the diseases discussed as to their connexion with optic atrophy were hereditary syphilis, epilepsy, insanity, and spinal diseases, while a special reference to hereditary ataxy was made. Collecting the evidence, he concluded that the hereditary nature of the affection depended on the transmission of a neurotic diathesis (the neuropathic type in which Leber classed the individuals), which left the patients specially prone to any exciting influence which was liable to affect the optic nerve. Exciting causes were looked for which had a depressing influence upon the nervous system in general. The influence of the sexual system was first discussed, and the liability to nervous disorders at the two periods of life represented by the disease was regarded as extremely significant. These influences were more potent in young men than in women, but he had been unable to find any case in which a disorder of vision could be attributed to sexual influences alone, because in most of the cases other common exciting causes (for example, tobacco) were present. An illustrative case of Mr. Nettleship's was mentioned. The more important question of tobacco as an exciting cause was then discussed at some length. In nearly all the families added by him to the previous literature of the subject, one or two of the individuals were smokers. The cases, if isolated and treated as cases of tobacco amblyopia (which they strongly resembled), would be regarded as instances of a bad or stationary type. Very similar cases existed, though rare, among juvenile smokers. Mr. Hutchinson had expressed the opinion that tobacco caused blindness owing to an idiosyncrasy which might be found in several members of a family. He would go further than this, for though when a depressing influence upon the nervous system was present tobacco might act as the exciting cause and induce the well-known form of amblyopia, still something more was needed to explain these non-retrogressive cases. He therefore considered that the evidence pointed to some peculiar inherited predisposition to pathological disturbances of the nervous system, the precise part of the nervous system (the optic nerve) being determined by the kind of exciting influence.

The following living specimens were shown:—

Mr. R. MARCUS GUNN: (1) Peculiar Dotted Appearance of both Retinæ with Retinal Asthenopia, illustrating the retroid condition described by him in the third volume of the Ophthalmological Transactions; (2) Chronic Abscess of Cornea.

Mr. NETTLESHIP: (1) Retinitis in Diabetes; (2) Persistent Hyaloid Artery.

Mr. H. JUKES: Retro-Bulbar Neuritis (?) occurring in a

Digitized by Google

young woman who had suffered from rheumatism recently. The blindness came on suddenly on Oct. 1st, and rapidly became worse for a few days, but was now passing away.

Mr. DOYNE: Hæmorrhage into Yellow Spot Region.

Dr. W. J. COLLINS: Central Detachment of Retina in Albuminuric Retinitis. This specimen led to an interesting discussion on a side issue—the prognosis in albuminuric retinitis.—Dr. Coupland and others believed that such detachments of the retina only occurred in cases associated with extensive dropsy, and he regarded the detachment as a dropsical phenomenon.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

A MEETING of the above Society was held on Friday, Oct. 21st, Dr. Alfred Lee, President.

At the first meeting of the session the PRESIDENT delivered an inaugural address, of which the following is an abstract. Having thanked the Association for the honour they had done him in electing him their President for the second time, Dr. Hill reminded his fellow officers that the electorate was this year extended by the amalgamation of the provincial associations of medical officers of health with the parent Society, though when he threw out the suggestion at the last annual dinner he had then no presentiment that realisation was so soon to follow the conception of the project. He heartily congratulated them on the change, because the union of their separate forces must naturally increase their strength and authority and develop their usefulness, while in no way interfering with the action of the individual branches, which now constitute the one body. Power was secured only by unity of action and concentration of effort, and their influence could not fail, therefore, to be more effective in a variety of ways than it had been in the past. The President then went on to indicate some of the directions in which their united energies might be advantageously employed, as, for example, in bringing influence to bear on the Legislature, in order to obtain the passing of new laws and the amendment of old ones affecting the public health, in approaching the Local Government Board, in improving their relation to the public press, in promoting or extending institutions having a scientific object (such as bacteriological, chemical, and other investigations serving to promote sanitary science)—in fact, in a great variety of ways their consolidation into one society, instead of frittering away their energies and resources, could not fail to prove highly advantageous. Dr. Hill mentioned, as a new feature of the Society, the proposed holding of a meeting annually in some provincial town, instead of, as hitherto, having all the meetings in London, and referred to the circumstance that whilst the provincial associations have not been able to see their way to the publication of many highly valuable papers owing to the expense attending it, it was now intended that the most meritorious of the papers read, not only before the Society, but also its branches, should be embodied in the Transactions. The speaker went on to say that it had long been felt that one of the great wants now experienced by sanitarians was a journal of public medicine. At present the abundant material for such a periodical is neither scientifically treated nor readily available, and he thought that under the new conditions of the Society the establishment of such a journal was more feasible than it ever had been, and with the advance of hygienic science much more necessary. Every hygienist had deplored, too, the non-existence of a physiological and pathological institute, properly furnished for the scientific investigation of many questions affecting public health. The subject of bacteriology was one that demanded prompt and thorough investigation; but, to effect this, much time, a properly appointed laboratory, considerable funds, special training, and undivided attention were necessary. A proof of the value of a study of micro-organisms had lately been afforded in connexion with that *opprobrium medicinæ*—autumnal diarrhœa. After alluding to the inquiry which the Local Government Board set on foot some seven years since, in search of the causes which contributed to the great prevalence of this disease, more particularly in certain of our large towns, and paying a graceful tribute to Dr. Ballard, who had charge of the inquiry, the President drew attention to the important results obtained from some bacteriological investigations made last year by Dr. Tomkins, the medical officer of health for Leicester, a town which has for many years suffered unaccountably from diarrhœa. In 1880 Dr. Johnston, the then medical officer of health, failing to discover the cause of autumnal diarrhœa, suggested with prophetic shrewdness that "the more immediate cause will be found, if I mistake not, to consist of fungoid impurities in the air derived from the putrefaction of animal refuse." Dr. Tomkins, pursuing this idea of the origin of the disease in low forms of life, found in his bacteriological examination of the air that in one part of the town a cubic metre of air contained from 60 to 900 germs, while in another part, in the same quantity of air, he found from 2000 to 7000, while the part of the town where this excess of microbes existed was the low-lying and flat portion, with sewers too small, deficient in fall, and constantly liable to stagnant deposits and overflow. In this area, which at a very liberal estimate did not contain more than one-third of the whole borough population, 216, or 84 per cent., of the deaths occurred. But the most valuable feature of the investigation is the production of diarrhœa by the administration of a very small dose of the growths obtained from the air of the contaminated part of the town, and from certain internal organs after cultivation through several generations. Dr. Hill went on to say that there was no doubt that the micro-organisms of sewer air, of rooms, and of drinking water all offer a prolific field of study, which as yet lies almost entirely unexplored. Did not all this show, he said, how great a desideratum an institution would be where such work could be systematically and efficiently conducted? There were many other questions, such as sanitary law and professional ethics, for the solution of which standing committees might be appointed. Dr. Hill next dealt with the important influence exerted on the public health by the generally bad condition of dwelling-houses, both old and new, and remarked that the happiest results would ensue if every sanitary authority would adopt and courageously apply *in toto* the bye-laws recently published by the Local Government Board. Having condemned the principle of the Bill recently introduced into Parliament, by which architects, surveyors, and others, as well as medical officers of health, could certify as to the fitness of a building for occupation, and contended that medical officers of health were the persons best qualified by their special knowledge and experience to do the work, the speaker proceeded to review some of the reasons why sanitary legislation often failed, and said that, though an ardent admirer of local self-government, yet the action of local authorities often needed such a stimulant as could only be supplied by the independent and firm action of a strong and wise central authority. As an illustration of bad local management Dr. Hill cited one recently furnished in a village in the north of England where typhoid fever was said to have appeared in nearly every house, and almost every conceivable nuisance to exist in close proximity to the dwellings. Proceeding to comment upon the groundless objections urged by the prejudiced or ignorant against vaccination, he expressed surprise at the views held by Mr. John Bright, as shown in a letter recently published, and said the final words of the letter—"I would not compel them to submit"—are calculated to do much mischief, coming from one so eminent. The effects, indeed, are already seen. The letter has already been distributed broadcast by the press, and is no doubt effectually working its evil influences. It is, in fact, difficult to feel sure that the anti-vaccinationists may not ultimately gain the day, especially when we bear in mind that the anti-agitators succeeded in removing the Contagious Diseases Act from the statute book. He urged upon his hearers to do all in their power to show the public how groundless was the contention that medical men profited by vaccination; that, on the contrary, they suffered pecuniary loss through the prevention of disease which it occasioned. Turning to the evidence that the sanitary situation of the day compared very favourably with that of past years, the speaker said that, going back no further than 200 years, we find that the death-rate in London was 80 per 1000, whereas now it is less than one-fourth of that amount; this improvement might be taken as an illustration of the general advance which had taken place during the last two centuries. Owing, however, to the impulse given by the terrible cholera visitation of 1832, this advance has been most rapid during the last fifty years, and the many sanitary laws passed during that period, all of which were cited, show that the Legislature has been willing, not merely to keep pace with public opinion, but actually to lead it. Dr. Hill concluded by reminding them that the Public Health Act of 1848 was a permissive one,

Digitized by Google

and that proposals to render sanitary legislation compulsory evoked great opposition, partly on the ground that the sanitary staff of that day was all that was needed, and that the salaries of medical officers of health would be simply money thrown away. Whether this was so or not he would leave them to judge by a comparison of the mortality figures of nine of the largest English towns during the ten years previously to 1875—i.e., before the passing of the Public Health Act of that year—with those for the twelve years since that Act came into operation. In the decade 1865–1874 the average death-rate of London, Liverpool, Manchester, Salford, Leeds, Hull, Glasgow, Edinburgh, and Birmingham was 27·8, in the succeeding decade it fell to 24·2, while the average of the last ten years was only 21·5. If the death-rate of the ten years previously to 1875 had been maintained during the following twelve years, the lives of no fewer than 247,346 persons who were living at the commencement of this year would have been sacrificed, while on Dr. Farr's estimate of £159 as the value of the average human life, the pecuniary value of the lives saved in these nine towns during the last twelve years of active sanitation represented very nearly forty million pounds. This takes no account of the enormous amount of suffering that has also been avoided. Sir Spencer Wells had estimated that two millions out of eight millions which the population of the United Kingdom had increased by during the last fifty years might safely be regarded as a very moderate estimate to set down as a clear gain due to sanitation, while he put the utility of sanitary action in a very striking form, by stating that the average duration of human life had risen during the same period from thirty to forty-nine years. Dr. Hill concluded by saying that though there was much ground for congratulation on what sanitary science had already achieved, it would not do for them to "rest and be thankful." Much remained to be done, both by way of improvement, extension, and initiation. The great object to keep in view was cleanliness—clean bodies, air, food, water, and dwellings.

ABERNETHIAN SOCIETY.

THE opening address at this Society was delivered by R. THORNE THORNE, M.B., F.R.C.P., at St. Bartholomew's Hospital, the subject being "Cleanliness in its relations to Health." The nursing staff of the hospital were present by invitation. The following is an abstract of the points dealt with in the address:—

Dirt being matter in the wrong place, and nature having allotted to every form of matter its proper place, such matter, it was held, only becomes hurtful to a man in so far as the well-ordered design of nature was interfered with. In elucidation of this principle the speaker entered at some length into the conditions by which the air of our towns and cities became fouled by crowding of houses on area and of persons in houses, the inhabitants inhaling each other's emanations, until typhus fever became a common and fatal disease amongst the destitute classes subjected to these uncleanly circumstances; and then taking the case of London, he showed how typhus had been practically extirpated as a current endemic fever by the measures that have been adopted during the past twenty years in the demolition of unhealthy property, the opening out of wide streets and other breathing spaces, and the provision of some open space to the front and rear of new dwelling houses. Liverpool taught the same lesson, but in a somewhat different manner; for whilst the typhus mortality of that city had, on the whole, undergone material diminution, the disease still caused a regular annual mortality, and tended to recur in limited epidemics, which constituted a danger to the kingdom at large. It was then shown by quotations from official and other documents how rife the conditions of uncleanliness with which typhus is especially associated still are in Liverpool. Coming next to the need for cleanliness in such matters as water supply and means for the disposal of the solid and liquid refuse of populations, the state of this country with regard to enteric fever at the present date was compared with that which prevailed before modern sanitary works had been carried out in a comprehensive and intelligent manner, and it was shown how great had been the saving of life from this once preventable continued fever as the result of the expenditure of public money in works of sewerage and water supply which had been voluntarily incurred by the people of this country, and which has cleanliness as its principal aim. Applying somewhat the same principles to the subject of house drains, the progress in cleanliness of the air of our hospital wards was discussed, and it was shown how, by means of cross-ventilated lobbies between closets and wards, and by means of an air-break between ward and drain, the sick were now no longer subjected to the inhalation of drain emanations. In the conflict with disease which each sick person is engaged in, the need for the utmost procurable cleanliness of air breathed was urged, and it was pointed out how, in modern hospital construction, it was now sought to attain this object. Coming next to details in connexion with attendance on the sick, the great importance of personal cleanliness was insisted on, and instances were given to show the dangers resulting from the handling of food supplies by those having charge of persons sick from infectious and other diseases. Cleanliness was to be aimed at in every detail, and the conditions under which some departments of modern surgery are carried out were instanced as types of that scientific cleanliness which should be observed in all our dealings with the sick. In conclusion, it was pointed out that nature is remorseless in exacting the penalty of disease and death for any breaches in her laws as to cleanliness; that the innocent suffer with the guilty; that unintentional acts, involving want of cleanliness in points of detail on the part of those devoting their time to the care of their fellows, are as swiftly followed by fatal consequences as is the crass neglect of those who deliberately violate every law of cleanliness by permitting the wholesale accumulation of filth about their dwellings; and that in order to remove such causes of preventable disease, it was above all things necessary to cope with the ignorance that prevailed as to the potency for mischief of dirt in all its forms.

Reviews and Notices of Books.

Zum Gegenwartigen Stand der Cholerafrage (On the Present Position of the Cholera Question). By MAX V. PETTENKOFER. Munich and Leipsic: R. Oldenbourg. 1887.

THE brilliant series of articles upon the subject of cholera by Professor von Pettenkofer, which he has been contributing to the *Archiv für Hygiene*, have been, at the wish of many friends, and to the decided advantage of sanitary workers all over the world, collected into one volume. In its present form this work constitutes, perhaps, the most important addition in modern times to the copious literature on the subject, for it not only makes clear the position assumed by the learned hygienist himself, but contains a full review of all other doctrines, which he has submitted to careful and impartial criticism. Our readers are already acquainted with the conclusions arrived at by Professor v. Pettenkofer, for a short time ago (THE LANCET, vol. ii. 1887, pp. 339 and 386) we published a digest of the articles which constitute the closing chapters of this work. It is therefore only necessary now to direct attention to the earlier portions of the book in order to show how the subject has been treated. In the first place this review is in the main limited to the facts and opinions that have been elicited concerning cholera since the epidemic in Egypt in 1883, and the discovery of the comma bacillus. The debates, conferences, and reports that have been held or made in Paris, Berlin, London, and Rome since that date have furnished a vast amount of material. From these it is possible now to distinguish two main doctrines—viz., that cholera is due to a specific virus having its habitat in India, and capable of being conveyed to other parts of the world by human intercourse; and the other, that cholera may arise spontaneously in any part, from telluric, atmospheric, and individual conditions, such as determine the milder disease, cholera nostras. Those who hold to this latter opinion Prof. Pettenkofer terms the *autocthonists*, while he would apply the term *ephodists* to those who attribute infective properties to the disease. He is constrained, however, to admit that the ephodists are of two classes: those, namely, who consider that cholera is transmitted from person to person (the *contagionists*); and those who consider that

Digitized by Google

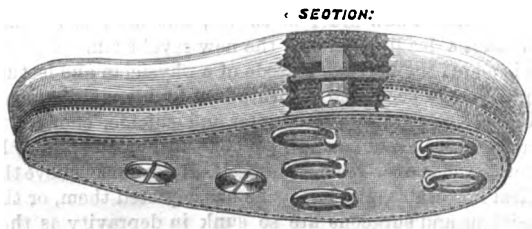
infectivity is inoperative unless the local conditions are favourable (the *localists*). Professor Pettenkofer himself is a determined localist, whereas Professor Koch is the chief exponent of the contagionist school. The monograph mainly consists in the detailed exposition of the doctrines thus severally held, with the arguments adduced in their support. The autocthonists form a select minority, but they have a powerful exponent in Dr. Jas. Cuningham, who refers the development of cholera to atmospheric and telluric influences. His views are well known; whilst, among others, the late Jules Guérin, in the debates at the Paris Academy, contested on behalf of the spontaneous origin of cholera. Having discussed these doctrines, Professor von Pettenkofer next deals with the contagionists, taking up in turn each of the main propositions in support of their teaching—such as the infection of the healthy by the sick, the excreta as the medium of infection, epidemics in hospitals and barracks as proof of contagion, infection through cast linen, ship cholera, dissemination by human intercourse, and lastly by infection of drinking water. It is needless to say that each of these points is thoroughly entered into; and with regard to some it is shown that too much stress has been laid upon exceptional instances, and with regard to others that a different explanation is forthcoming. Thus, as regards personal contagion, it is clearly shown that doctors and nurses are no more prone to cholera than those who are not engaged in constant attendance upon cholera patients; that the occurrence of cholera on shipboard is paralleled by cases of malaria which are known to occur occasionally under like circumstances; and lastly, that the drinking-water theory—which the Broad-street pump did so much to support—does not necessitate the adoption of the contagionistic doctrine. Turning next his attention to the position of the localists, Professor v. Pettenkofer furnishes a full account of the views which he himself has always been foremost in advocating—the influence of locality, of soil and drainage, and the support to these views derived from the history of epidemics. Besides discussing these subjects, he devotes a section to theories of cholera before entering on the summary, which we have already analysed.

St. Bernard's: the Romance of a Medical Student. By ÆSCULAPIUS SCALPEL. London: Swan Sonnenschein, Lowrey, and Co. 1887.

THE life of the medical student of the present day is more prosaic than it used to be, and less fitted than formerly for the pen of the novelist. The increased stringency of examinations, both preliminary and professional, has done something doubtless to effect this change, but the whole tone and tenour of student life has also vastly improved. It was therefore with pain and disappointment that we read the pages of this latest romance. The author is apparently a man of culture and wide reading, whilst Browning seems to be his favourite writer, if we may judge from the number and variety of quotations from that poet. But the work is not redeemed by these features from being a gross calumny upon medical students and their teachers; upon hospitals and their staffs. As an instance we may take the account given of a certain "Dr. Robert Day," who is readily recognisable from the statement that having been a successful teacher in Edinburgh, he was compelled to eke out a precarious existence in London from the odium incurred through his alleged complicity with the resurrectionists. The thinly-veiled pseudonym affords no disguise; but it is uncharitable, to say the least, to hold up this man, who retained a dignity in spite of his misfortunes, as an atheist and a revolutionary. For this is what his own pupil and friend says in the biography of the anatomist, published in 1870: "Without any outward religious manifestation, K—— was nevertheless a man of high reverence and belief"; and again, speaking of his conversation on high topics, he says, "In his hours of communicativeness, and where more was meant than meets the eye, on matters of revelation the Deistic feeling seemed to predominate in K——'s mind." It is surely not good taste, even in a romance, to so pervert the character of a man who, although not professing an orthodox faith, is here depicted (p. 56) as "an atheist, a dogmatic atheist, interested not merely in denying the God of the Bible, but in proving the existence of any supreme being at all." This, however, is but a small point in the whole, although it may fairly be taken as a sample of the amount of fact (!) which underlies the fiction. Briefly put, the medical student whose life is described is represented as losing his faith by contact with the materialism which springs from anatomical studies; he is drawn away from his high ideals by associating with the students (whose greatest exploits are knocker-wrenching) and with Socialists, male and female, to whom he is introduced by Dr. Day and his daughter. Further, in his hospital experience, he meets on all sides with nothing but callousness and indifference to suffering and a brutal desire on the part of house surgeons (!) to maim their patients without cause, in order to add to their list of capital operations. The physicians and surgeons of St. Bernard's are of the same inhuman type, so that we can hardly wonder at the hero of the tale, who comes to his senses after taking an active part in a music-hall riot, shaking the dust of such an institution off his feet and mysteriously burying himself in Spain for a number of years, until he is discovered by a like-minded young lady, the only daughter of a late physician to St. Bernard's, and possessed of great wealth. She, too, is struck with the inhumanity of the prevalent hospital system, and not only spends her fortune in seeking to supplant this by the foundation of a new order of things, but marries the man who takes a leading part in the new revolution. When to this is added the horrible episode of a physician and lecturer on physiology becoming so brutalised by his vivisections as ultimately to commit wife murder and suicide, enough, we think, has been said to show that the author, in spite of his cleverness, has over-reached himself. He cannot believe that clinical hospitals are as bad as he has depicted them, or that physicians and surgeons are so sunk in depravity as those who figure in his pages; and, what is more, he will not succeed in making any sane person believe it either. The book will serve no useful purpose, for it bears with it its own condemnation.

A Text-book of Organic Materia Medica. By ROBERT BENTLEY, M.R.C.S. Eng. F.L.S. Pp. 415. Longmans, Green, and Co. 1887.

THIS book is described both upon the title-page and in the preface as being systematically arranged, and especially designed for the use of students. It goes without saying that with Professor Bentley's experience of botany the systematic arrangement is fully carried out; indeed, as the botanical editor of the last edition of the British Pharmacopœia, he is essentially the right man to rearrange systematically the facts which we have before (in part) received alphabetically. Of the author's work in this direction it is impossible to speak too highly; his table of contents is in itself a study of botanical arrangement, and well repays the labour it must have cost. The descriptions of the general characters of the plants or parts of plants employed are full and yet clear and concise, the author's experience with several botanical handbooks having given him a power of lucidity which renders his descriptions elementary, and at the same time thoroughly practical and accurate. As a student's text-book however, or at least for medical students, it may be doubted whether the fulness of information does not occasionally pass beyond the limits of desirability—e.g., when we are told that a tree is "frequently



Digitized by Google

planted near the Hindoo temples," or that a substance is "imported from the United States in bales, casks, or bags," or that another is "finally packed in hempen sacks, called *bags* or *pockets*, for the market." On the other hand, the official preparations are noticed all too briefly; sometimes the doses are mentioned, more frequently they are omitted; mostly the compositions, even the amounts, of important ingredients like opium, are ignored. The alkaloids present in cinchona barks are enumerated, but no mention is made of their properties or actions. The medicinal properties are given very briefly and imperfectly; citrate and other salts of caffeine are said to be "in some use as nervine stimulants," and no mention is made of their employment for other purposes. The book is well illustrated and carefully printed on good paper. As an interesting work of reference it will be of much service, but as a text-book for medical students it is too unequal, too full in some particulars, too brief in other directions.

New Inventions.

DAW'S TRUSS.

IN consequence of the difficulty in procuring a truss with a pad capable of affording a complete sense of comfort, Mr. Thomas George Daw has invented an improvement in the form of the pad, which enables the wearer to alter the pressure according to his will within the area covered by the pad. The illustration shows the arrangement by which this is carried out, and the pressure may be adjusted to any degree. This is accomplished by screws and projectors fitted between the padding and the pad-plate, the means for turning the

screws being on the outside of the pad-plate. By turning a screw to the left, the projector forces that part of the pad against which it acts outwards, giving it increased pressure. The screws have a fine pitch, giving the projectors the means of delicate adjustment, and offering great stability to the parts projected. This pad can be applied to the ordinary truss spring, and will be found useful in many cases where the ordinary pad is not worn with comfort.

ALLEN'S SURGICAL PUMP.

ONE of the best things exhibited at the American Medical Congress was this invention. It is simple in principle, effective in working, and can be applied to a great variety of purposes. It consists of a piece of india-rubber tubing passed through one and out at another opening in a metal box or case. A handle with a crank movement brings a roller in contact with the interior coil of indiarubber tubing enclosed in the metal case. In revolving, the roller subjects the tubing to pressure, so as to close the calibre of the tube, and in that way a powerful aspirating effect is exerted. By a simple mechanism the roller can be brought into different degrees of contact with the tubing, or, when not in use, altogether set free from it. One side of the metal box can be easily removed, so that the internal mediastinum can be at once got at, and the tubing removed and replaced by a fresh piece as often as necessary. It is easy to see that by the addition of a few details the pump, the action of which can be at once reversed or made to move either way with equal facility, can be applied to numerous purposes. For instance, it can be used with trocars and cannulas in the surgical treatment of empyema, in dilating the urethra or uterus, in transfusion of blood, in cupping, as a lithotrity evacuator, or as a stomach-pump and enema syringe, and so on. The apparatus is difficult to describe without the aid of plates, but the principle of its action seems so simple and certain that we do not see how it can fail to attain the various objects to which it can be applied. One of the delegates to the American Congress brought away a case containing Allen's surgical pump fitted with all the appliances (which are, after all, of a very simple and inexpensive kind) necessary for fulfilling the various objects for which it was designed; he has been good enough to demonstrate its use to us, and we can consequently speak from personal knowledge of its merits. We confidently predict that it will be appreciated in this country as soon as these merits are known; and we may in the meantime recommend any of our readers to obtain one of the cases fitted with the surgical pump in question, together with the other articles accompanying it, and try it for themselves. We do not think they will be disappointed. It can be obtained of Messrs. Chas. Truax and Co., surgical instrument makers, 75 and 77, Wabash Avenue, Chicago, Ill.

DRAKE AND HASSAM'S PATENT BRONCHITIS KETTLE AND FOOD WARMER COMBINED.

OUR attention has been drawn by the patentees to a new bronchitis kettle, which appears to have many advantages over those ordinarily in use. At one side of the steam-generating vessel a round orifice is made, lined with tin, going nearly to the bottom of the vessel. Into this orifice a vessel or saucepan is inserted to hold beef-tea, milk food, or any delicacy required to be kept hot in the invalid's room, without occupying any more space on the stove or necessitating another fire, as the saucepan does not interfere in any way with the steaming powers of the kettle. An important improvement is the telescopic tube, which can be drawn out or pushed back without any loose parts to get mislaid or lost, and the kettle when out of use occupies very little more room than an ordinary one. The vaporising chamber at the extremity of the tube is intended to contain cotton wool saturated with any medicament prescribed, and is so arranged that it does not check the free passage of the steam through it. The kettle is well made, and its cost is moderate. The patentees are Messrs. Drake and Hassam, Churton-street, Belgrave-road, Pimlico.

THE THERMO SAFEGUARD FEEDING-BOTTLE.

THE patent thermo safeguard feeding-bottle, made by Messrs. Pocock, Keevil, and Co., 72, Wandsworth-road, S.W., is chiefly valuable on account of its permitting the temperature of the food to be ascertained by the nurse whenever the bottle is put into use. The thermometer is so embedded in the bottle as to constitute an integral part of it. In addition to the thermometer, the bottle possesses the advantage of being graduated in ounces, so that the precise amount of food administered can be known. There is no objection to the shape of the bottle, which has many points to recommend it. For ourselves, we think it best to abolish the tube and to have as few indiarubber fittings as possible—indeed, the teat should be the only indiarubber portion. The slipper-shaped bottle is the best, despite its being a little awkward to use.

A PASTEUR INSTITUTE FOR RIO DE JANEIRO.—The Brazilian Government has arranged to establish a Pasteur Institute for the inoculation of persons bitten by rabid animals, and has appointed Dr. Pereira dos Santos, a pupil of Pasteur, as director.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, OCTOBER 29, 1887.

Now that the vacation is over, and the medical schools are again in full session, the agitation for obtaining degrees for London medical students will soon recommence. We would therefore remind our readers of the present position of this important question, or rather questions, for the two considerations of granting degrees to London medical students and of establishing in London a new university, which shall be modelled on the Scotch and provincial universities, and thus be a true Teaching University, are indissolubly interwoven. The power of granting degrees to London medical students is eagerly desired by almost every medical teacher in London, although there may be some difference of opinion as to the conditions and methods by which this would be best obtained. The two Royal Colleges of Physicians and Surgeons have agreed to ask for this power to be conferred on them, and a representative committee of delegates has held many meetings to consider the desirability and practicability of granting degrees in Medicine and Surgery to persons who have passed the Conjoint Examinations of the two Colleges. A petition has been laid before the QUEEN in Council, praying for a new Charter, a copy of the draft of which we printed in our issue of July 2nd, p. 37. In fact, the Royal Colleges ask to constitute themselves into a University with one faculty only—viz., that of Medicine,—and are silent as to the needs of teachers and students in Arts, Science, and Laws. The demand for a degree for London medical students is to them a purely professional one, and is the only one to which the Colleges have to pay attention, for their concern is with the medical aspect of the question alone. The sufficiency of the Conjoint Examinations, the unrivalled clinical advantages for medical education in London, and the eminence of the clinical teachers are the great grounds on which they ask for this power, and most persons will allow that they form a valid reason for the giving of a degree to a London student on the same terms as his competitor in Scotland or in the provinces can now obtain it. But to the scheme of the Royal Colleges there are a multitude of objectors, some making use of merely selfish arguments, and others treating the question from a wider and more academical point of view. The Irish and Scotch Colleges of Physicians and Surgeons demand a similar privilege if a Charter be granted to the English Colleges. The Scotch Universities, and most authorities on education in this country also, are objecting, either actively or passively, to the granting of degrees by purely professional corporations, and to a one-faculty University. The provincial schools say that they form an integral part of these corporations, and so cannot allow them to give exceptional advantages to students educated in London. Manchester, Birmingham, Leeds, and Bristol send members of Council to both the Colleges of Surgeons and Physicians, and they urge that the students at these provincial schools must be admitted to any qualifications or degrees granted by the corporations on the same terms as those which apply to London medical students. Hence the protests against this power being conferred on the Royal Colleges are very numerous, and come from widely different quarters. The University of London says nothing officially about this scheme, but seems to regard it as one for the institution of an inferior degree, with which they have no concern.

More especially anxious for the formation of a new Teaching University in London, of which they would constitute the most important factors, University and King's Colleges have come together, and have also submitted a draft Charter and a petition to the QUEEN in Council. They ask for powers to constitute a new university, of which they would form the Faculties of Art and Science, whilst all the medical schools in the London district would form the Faculty of Medicine. The representatives of the Royal Colleges might be considered the representatives of the London Medical Schools, or they might be chosen directly from the schools. This project has the advantage of not being opposed from the professional corporation or the single faculty standpoint, and is strongly supported by those interested in the formation of a real Teaching University in London. It has also the sympathy of those authorities on educational progress who believe that proper teaching must be by systematic courses, and that examinations are only an imperfect substitute for real teaching and the personal influence of able professors and lecturers. The University of London, however, dislikes this new movement, and, not wishing to see its two most important London Colleges withdraw from under its wing (although the connexion is at present merely nominal) and follow the lead of Owens College, has asked for opportunity to show cause why the prayer of University and King's Colleges should not be granted. The University of London has departed from its original function and become an Imperial Examining Board, and cannot do anything in the way of uniting or co-ordinating the teaching bodies in London; hence the need of a new institution for this work. As for the multiplication of small universities, which some dread, a new university in London and a university in the midlands are required to place England on the same footing as Scotland and Germany, and, to judge from the short history of the Victoria University, nothing but good would be the outcome of their establishment.

The institutions interested in this movement are so numerous, the conflict of opinion is so great, and the standpoints from which they are argued are so various, that a Royal Commission will probably be required to inquire into the whole bearings of the question. We can but express our regret at the loss of Dr. MOXON and Dr. WILSON FOX and the illness of Sir WILLIAM GULL, who all took a keen interest in the question.

IT goes without saying that an art—or, more accurately, an applied science—which concerns man as a physico-mental organism, must be cosmopolitan. Only in so far as racial peculiarities and topical conditions may modify the development of this organism can there be anything national or local in the character of medicine. Moreover, although there will necessarily always exist a certain amount of

Digitized by Google

rivalry between nations, and we are not prepared to say that this competition is undesirable in the interests of progress, nothing like exclusiveness can reasonably exist in reference to a matter which is of general concern. It is always well to try questions of this sort thoroughly, and if we apply a crucial test the wrongfulness of any limitation as regards medicine will be instantly apparent. Thus, suppose for a moment it were possible that the physicians of any one nation should become possessed of a special remedy or process of treatment for the relief of pain or the cure of disease, it would be a crime against *humanity* for them to keep their knowledge secret. The medical sciences and arts stand on a footing which makes them common property. This cannot be said of any other department of knowledge, except perhaps religion; and the same feeling which compels a sincere believer to propagate his faith must make it incumbent on a physician to place the whole of his knowledge at the disposal of all other physicians without regard to place or people. Whatever rivalry there may be must relate to enterprise in the acquisition of knowledge, not to the advantages accruing to its possession. Practically this is generally recognised, but there are, nevertheless, considerations that ought to have weight in reference to the subject in question, and which it may be worth while to suggest.

The fact that medicine is cosmopolitan, in a sense in which universality cannot be predicated of any other department of discovery and progress, implies that not only the science and art, but the profession and great body of practitioners in all countries are *one*. This is true in regard to our cloth as it is true of no other. Even the priest or minister of religion has his shibboleth, and he cannot go far without encountering some other priest or minister who, from his standpoint, is heterodox. The physician cannot find in the wide world any educated practitioner with whom he is not on the common footing of a fellow-student. The only qualification to this statement relates to those who attempt to set up "pathies" or systems. This is why—and the only reason why—the profession sets its face resolutely against any endeavour to introduce the sectarian element into medicine. A man may believe or disbelieve what he pleases, provided only that he does not erect his belief into a "system" or combine with his followers to form a sect. Rational medicine is the outcome of a study of health and disease, and whatever differences of opinion may exist between students or practitioners must be the results of differing degrees of acquaintance with natural facts, or with various phases of the same facts as seen from diverse standpoints. There are different developments of knowledge among us, and special forms of disease are indigenous in certain localities or peculiar to particular races of man; but the differences of view and judgment which arise out of these diversities of the subject do not affect the underlying principles of our science, because we are all studying nature, whose manifestations are, *cæteris paribus*, the same everywhere. Particular views may prevail in certain countries and among special communities, but they are either the effects of isolation, or they are specialities of truth proper to the local conditionings of fact. Although the differences of doctors are proverbial, there is positively no other profession which is so united, or which makes so near an approach to a community of aims and interests as the medical.

The cosmopolitan character of medicine implies much more than international courtesies and friendliness among the physicians of all countries. They are bound together by a common purpose—namely, the relief and remedying of physical suffering; and of late years a new and most potent interest has been superadded, with the aim to eradicate disease. For success in this last-mentioned enterprise, even more markedly than in respect to other of our endeavours, we are dependent on mutual help and sympathy. It is obviously impossible to fight the battle against disease, as a whole, effectively, unless we all unite to further the common object by every means in our power. Nothing but good can result from the cultivation of a spirit of unselfish amity among the physicians of all nations. There must be no jealousy or distrust; no unfriendliness or suspicion of any kind ought to be tolerated. Some may have had advantages in one way, some in another. What one shall chance to lack the other ought to be glad to compensate. Our indebtedness to the industry of the German physiologists, pathologists, and chemists is so great that it cannot but be acknowledged; yet this cannot inspire us with any feeling of chagrin or dislike. On the contrary, it binds us to them as learners to a teacher, and if in our time we can contribute anything to the common fund we are too grateful to be in the least degree elated with our success. To the physicians and surgeons of other nations, the French, the American, the Dutch, the Russian, and others, we are likewise related as recipients, and, possibly, also as the contributors, of knowledge. It must be ever thus, and the sole anxiety should be to increase the obligation on all sides. The great International Debt of science is one that brings nothing but good in its train, and those are the happier and the more prosperous who make the largest investments and are the largest holders. In the interests of science and for the benefit of suffering humanity, it cannot be too widely and practically recognised that medicine is cosmopolitan, not merely as an accident of its development, but as an essential fact and consequence of its very nature as the applied science of health preservation and recovery for man.

THE subject of sea-sickness has recently been receiving special attention, both in this country and in America, our own columns bearing witness alike to the interest felt in the question, and its highly speculative character. It is somewhat singular that although we are the most seafaring nation in the world, and although *mal de mer* is one of the most frequent and most distressing of maladies, we are by no means certain of its pathology, and no plan of treatment hitherto devised has been successful in commanding general acceptance. It may not, however, be without advantage to recall some of the most plausible theories regarding the causation of sea-sickness, and some of the therapeutic measures which have been advocated with more or less confidence.

Broadly speaking, there are but two theories regarding its pathology (each, however, with some modifications in detail), one assigning the malady to gastric irritation, while the other regards some disturbance of the nervous mechanism, whether of the cerebro-spinal or sympathetic system, as its efficient cause. According to the former view, the motion

Digitized by Google

of the vessel causes some disturbance of gastric digestion, resulting in nausea, vomiting, and the long train of disagreeable symptoms with which all are familiar. Of those who lean to this theory, some regard the churning up of the contents of the stomach as the essential point, while others suggest that there is relaxation of the pyloric sphincter, and hence a flow of bile into the stomach. In favour of this theory are the facts that many sufferers describe the gastric symptoms as first in the order of time, that pre-existing digestive disturbance or constipation undoubtedly increases the tendency to the affection, that "bilious" people often suffer very severely, that bile is occasionally present in the vomited matter, and that pressure or counter-irritation over the stomach, combined with gastric sedatives, has met with some success in the hands of various practitioners. On the other hand, the objections against regarding sea-sickness as a purely gastric affection are many and weighty. The facts that women suffer out of all proportion to men, and that young children are almost wholly exempt, are difficult of explanation on the theory that mechanical agitation of the contents of the stomach is the efficient cause of the malady. Violent exercise of various kinds must cause an amount of gastric disturbance at least equal to that produced at sea, but nausea and emesis do not ensue. Again, it is not denied by any that nervous apprehension of the malady greatly increases the liability to it, or that it not very rarely occurs during perfectly calm weather at sea. Nervous, excitable women have certainly been known to suffer on shipboard even before the vessel had begun to be in motion. If we inquire carefully into the clinical history of these cases, we shall find that in a very large proportion the first symptoms are commonly cerebral, violent vertigo being one of the most frequent. The above facts are hardly reconcilable with any theory of sea-sickness which professes to explain it as the consequence of mechanical disturbance of the contents of the stomach.

Of the theories of the causation of this malady which refer it to the nervous apparatus there are at least three: first, that it is due to paralysis of the sympathetic system; secondly, that it is due to disturbance of the circulation in the brain-substance; and thirdly, that its true cause is to be sought in some interference of equilibrium in the fluid of the semicircular canals. This last theory, which has enlisted many advocates, draws its support mainly from the analogy of certain symptoms found in MENIÈRE'S disease and cognate affections of the internal ear with those of sea-sickness. Of the two former "nervous" theories it is sufficient to remark that they are not necessarily mutually exclusive, and that, taken together, they account perhaps better than any other hypothesis for the long train of complicated symptoms which unite to constitute *mal de mer*.

Turning to the question of treatment, we find the whole subject in a chaotic condition. Sedatives and tonics of the nervous system, gastric sedatives, stimulants, counter-irritation either of the abdomen or head, pressure over the stomach by pads or stays—these and a host of other measures have been vaunted as specifics by one authority, and in turn ridiculed as wholly worthless by another. Of the drugs recommended with more or less confidence, we may mention bromide of potassium, chloral, chloroform, nitrite of amyl, pilocarpine, strychnine, atropine, caffeine, bismuth, cocaine,—to choose a few out of a list whose length suggests reasonable doubts regarding the pre-eminent virtues of any single medicament. Probably some or all of the drugs mentioned may find their use in combating some of the effects of sea-sickness; but we must have much more definite proof than any yet forthcoming before we can accept any single remedy as in any sense a specific. It is worthy of note that sailors have no favourite remedy for sea-sickness, which they invariably regard as a necessary discipline through which the majority of seafarers must be content to pass. With the enormous experience of the malady which every day affords, it is difficult to believe that the sovereign virtues of any specific—should such be discovered—would long fail to command universal recognition.

If specific treatment is still *sub judice*, there can be no doubt that much may be done by way of relief and palliation. Any dyspeptic symptoms, especially constipation, should as far as possible be subdued before a voyage is undertaken. Efforts should be made to allay undue nervous apprehension. The food taken should be such as the stomach can readily tolerate and assimilate. The sufferer should seek and keep the recumbent position—preferably, if the weather permit, upon a couch or easy chair on deck. Pressure or counter-irritation over the stomach may sometimes be tried with advantage. Ice and dry champagne—part of the undoubted value of the latter being probably due to the carbonic acid which it contains—are useful. If the vomiting become very spasmodic, sedatives may be tried. In the adoption of other lines of treatment the practitioner must be guided by the symptoms present in each individual case.

AMONG the pursuits open to women and highly fit for them that of nursing stands conspicuous. The demand for nursing is one of the demands of the generation. In the time of our forefathers few ventured to indulge in a nurse. Such a luxury was reserved for hospital patients and lying-in women. And even then the nurse was a very different person from what she is now. She was sometimes intelligent and resourceful, tender in touch, a kind of mother where the natural mother was not forthcoming or available. She was sometimes *that*. And sometimes she was altogether otherwise—coarse in manners and in touch ignorant and superstitious, vulgar and intemperate in habits, and rough in speech; given often to heavy and perhaps snoring sleep at those critical hours of the night when fever and delirium and pain do their worst, and the patient needs a watchful friend.

It is strange that society should so long have borne with nurses so uncongenial and so incompetent. In fact, it was afraid of the class, and the fear still survives. Old-fashioned people can scarcely be persuaded even now to trust themselves, especially in the night, with a professional nurse. But things are altering fast. We have heard of an eminent physician, who in the occasional illnesses from which even eminent physicians are not exempt, betakes himself to bed, sends for a good nurse, and so waits patiently till he is better. A large section of intelligent people are beginning to see the wisdom of such conduct. Under the guidance of his medical practitioner it not only secures the best attention to the patient, but it saves the health of other members of the household whose illness would

Digitized by Google

involve the most grievous complication of the patient's distress, and fits them the more for daily services in the sick room when the nurse is having her much-needed rest or exercise. People who act so, and are fortunate enough to get a good nurse, find that they have got a veritable friend, and often a lasting one; and the people who act so are becoming more numerous every day. In a remarkably neat little pamphlet before us is an admirable address on the "Duties and Conduct of Nurses in Private Nursing,"[1] by Dr. W. L. RICHARDSON, of Boston Massachusetts, in which the writer tells us that in Boston, with, perhaps, 400,000 inhabitants, on May 13th, 1886, there were 163 trained nurses on the register, and only ten of these were disengaged, and several of these had only just become free. The supply there falls short of the demand. There are in the United States alone more than thirty training schools for nurses, which, it is gratifying to read, took their origin in imitation of the first English Training School for Nurses, founded in honour of Miss FLORENCE NIGHTINGALE in connexion with St. Thomas's Hospital in 1860. Those who are practising, or intend to follow, the calling of nursing should read the Address we have mentioned. If they can receive it, and enter into the spirit of it, the remaining prejudice against trained nurses will soon pass away. We gather that in the United States, or at least in the Boston Training School for Nurses, two years' training is thought necessary. It is curious that, whereas less time is required for medical education than in this country, more is required for the education of nurses. But this is only by the way. What we so heartily admire in this Address is the exposition of the spirit in which the study of nursing and the practice of it should be carried out. The candidate or probationer is to aim at being the best nurse, at learning her work thoroughly, and, when she has done so, at doing it in a spirit of the greatest gentleness and serviceableness, not only towards the patient, but also the members of the patient's household. Part of the prejudice against nurses is due to a certain mechanical routinism with which many nurses go through their duties to the patient, and part to an unsympathetic attitude towards the other members of the household, who have a most natural hesitation in abandoning their nursing duties to a stranger. It is the misfortune of the nurse, unlike the doctor, that she comes into the sick house as an absolute stranger. A really wise and kind nurse sees this, and makes allowance for and soon overcomes the natural prejudices of friends, and even of servants, who are apt to think that a nurse is exacting and unsympathetic towards them. The proof that nurses generally are better trained is in the fact of the rapidly growing appreciation of their class, and the demand for their services. They have little excuse now for being unpopular. The work of FLORENCE NIGHTINGALE, and the devotion of thousands of ladies, of every denomination, to nursing work, invest their calling with a charm which the slightest tact on their part will enhance.

Mr. H. C. BURDETT has announced a benevolent proposal to make the prospects of nurses more comfortable in a financial sense. He does not give us the details on which he proposes to base a system of provision for days of age and infirmity. There can be but one opinion of the desirableness of such a provision if it can be well based. Mr. BURDETT sees in the Women's Jubilee offering and the QUEEN'S views as to its disposal the possible basis of such a fund as will guarantee to certificated nurses beyond the age of fifty a pension proportionate to the contributions which they have made. He would be content with £20,000 out of the £75,000 which her MAJESTY has determined to devote to the benefit of nurses and nursing institutions. It is for nurses themselves, under the advice of actuaries, to say whether a special fund is better than insurance in some ordinary way, as the Post Office or the insurance offices, which guarantee the payment of a sum at a given age on condition of regular payment over a series of years. There seems an extensive desire on the part of nurses to join in a pension scheme of their own. The gracious intention of Her Majesty presupposes an organisation that will command public confidence and, at the same time, represent nurses widely and faithfully. Whatever the organisation the QUEEN may choose as the medium of her bounty, she has already indicated her respect for nurses as a class, in which, as in so many other matters, Her Majesty well represents the public sentiment.

THE struggles of administrators of public health legislation are well depicted in DR. ALFRED HILL'S presidential address to the Society of Medical Officers of Health last week. These officers may congratulate themselves on the past, and may regard with satisfaction diminished death-rates and reduction of disease, but they must never rest and be thankful; it is their duty everlastingly to persevere in the work of improvement, and for this there is no finality. Their difficulties are not due to an unwillingness of Parliament to arm those they serve with the powers they would desire, and on this point Dr. HILL was able to cite the numerous measures which had been passed, and which were still being passed, to further their work. Nevertheless there was failure, and the failure arose chiefly from the ease with which sanitary authorities could evade enforcing laws of which Parliament had recognised the importance. Sanitary legislation was always permissive and never compulsory, and it was often impossible to induce the local bodies to give facilities for these laws to be administered in the districts they controlled.

The fault, if there be a fault, is in the fact that health has only recently come to be appraised at any value and that the present generation is only beginning to claim a right to have their lives protected against disease as well as against violence; but this claim having come, it is well to see that the machinery exists which will enable it to demand a sufficient hearing. There is no probability that for many years to come the adoption and enforcement of sanitary laws will be made compulsory: as Dr. HILL himself says, society is not ready for it. Admitting this, it is the more necessary that the bodies which are to control the health condition of districts should be constituted in such a manner as to give reasonable promise that they will perform the duties for which they are appointed; this much devolves upon the statesman, and not upon the health officer. The improvement of areas, and the ensurance of a permanent tenure of office by those whose duty it is to advise local authorities, are absolute essentials for successful work. At

Digitized by Google

the present moment the health officer is working under difficulties which are not apprehended by the general public. His liability to removal from office if his views are more advanced or his energy more pronounced than is desired, and the system of his election for a period of two or three years, tend to militate against the freedom of his action and the proper performance of his duties. Even where central control is exercised, it is not always attended with success. England affords but too many examples of the dangers of partial control—of a control which serves rather to deprive local authorities of their sense of responsibility, than to lead them to adopt the course which it is desired they should follow.

Dr. HILL has, however, pointed out another requirement of the health officer upon which the future of public health must largely depend—the education of the officer himself. It is no exaggeration to say that his opportunities for this purpose are in England far behind those of many other European nations. In many cases he begins his duties so imperfectly trained that he has to learn his subject after he is appointed to his district; and it is, indeed, matter for surprise that, under these circumstances, the results to which Dr. HILL could refer have been attained. But, in dwelling on the need for the local officer to possess adequate knowledge, we would desire to go further and claim for the Central Board that its opportunities for studying the etiology of disease should be very largely increased. Our statesmen are not always prepared to recognise that knowledge should precede legislation, and are too ready to consider the inconvenience which may result when such knowledge exhibits their procedure in an unfavourable light. But if there is to be progress in the prevention of disease, if local authorities are to be expected to be more zealous than heretofore and their efforts to be more productive of good, the maintenance of an intelligence department is an absolute necessity. The branch of administration that has until now been engaged in duties of this nature has by the excellence of its work proved the advantage which results from the scientific investigation of disease, but its powers have been more limited than they should be in the future, and it has been crippled by alliances which ought never to have been formed. The health officers who listened to Dr. HILL'S address may well demand that experience gathered from all parts of the country should be placed at their disposal, and that of the districts they serve, and that precise information should be obtained on all points upon which they have to advise their authorities.

Already there are disquieting rumours that an unwise economy is threatening to diminish the prospect of further lessons being learnt. We may still hope that so short-sighted a policy will not be finally adopted, but if it should be found that the rumour is based on fact, we may hope that the health officers of the country, strengthened by the combination they have formed among themselves, and of which Dr. HILL tells us, will not hesitate to use their influence for the prevention of an occurrence so detrimental to the public interest.

DR. T. GRAINGER STEWART, Professor of the Practice of Physic in the University of Edinburgh, has been gazetted Deputy Lieutenant for the city and county of Edinburgh.

Annotations.

"Ne quid nimis."

THE GENERAL MEETING AT THE ROYAL COLLEGE OF SURGEONS.

THE Committees of the Associations of Fellows and of Members of the Royal College of Surgeons have agreed to move the following resolution at the general meeting to be held on Thursday next, Nov. 3rd:—"That this meeting disapproves of the application for a new Charter which, *first*, does not confer electoral powers upon Members of the College and the right to be eligible to sit in the Council in accordance with the resolution passed at the general meeting held on Nov. 4th, 1886—namely, 'That it would conduce to the welfare of the Royal College of Surgeons, and would tend to promote the interests of medical polity and education—(1) if Members of the College were empowered to take part (separately or conjointly with the Fellows) in the election of members of the Council; (2) if Members of the College were eligible to sit in the Council, provided (*a*) that no Member of the College shall be entitled to vote till he have been such member for a period of ten years; (*b*) that no Member of the College shall be eligible to sit in the Council till he have been such Member for a period of twenty years; and (*c*) that not more than one-fourth of the Council shall consist of Members of the College who are not also Fellows;'—and, *second*, which does not provide that no alteration shall be effected in the constitution or in the relations of the College, or in any of its bye-laws, without the consent of the Fellows and Members convened to discuss such alteration in accordance with a resolution passed at the general meeting held on March 24th, 1884, and reaffirmed at the meeting held on Oct. 29th, 1885." In the event of this being carried, it will be proposed that a copy of the resolution shall be sent to the Lord President of the Council by the Secretary of the College, and also that a deputation shall be nominated to wait upon the Privy Council in order to represent the opinion of the meeting.

SIR WILLIAM ROBERTS ON ALCOHOL.

OF all the things that are most "spoken against nowadays, perhaps alcohol is the first. It has been called the "devil in solution." But that does not prevent the medical profession from "giving the devil his due," and accordingly, though it has been extremely careful of late years in the prescription of alcohol, and much given to the curtailment of its use, even when patients thought they were using it moderately, some of our greatest physicians and surgeons have felt constrained to testify in its favour, and to argue that it has, or must have, some virtues, not only as a medicine, but as a drink and as a diet. The latest instance is not the least significant. Sir William Roberts delivered last week, to the Medical Society of University College, an address on Alcohol from the point of view of History and of Natural History. The burden of Sir William's argument was that nations which use alcohol compare favourably with nations that do not. Their achievements are greater, and their rate of mortality is less. The nations which use most alcohol show the smallest death-rate. Sir William said truly that the bad effects of alcohol were obvious enough. They obtrude themselves in every street and on every family. The coarse lesions of excessive drinking are the most obvious things in the dissecting room or the pathological museum. But it is not so easy to be just to the good effects of alcohol. They are not so palpable, but they may be equally actual. It may ward off disease, and it may offer effectual resistance when

Digitized by Google

disease invades the frame. It may contribute to a bolder, braver, and more powerful national history. Such an argument is, of course, not new. It recalls the arguments of Sir James Paget, the late Dr. Moxon, and others a few years ago. It is what many think, but what all have not the courage to say in face of a public opinion strongly urged to a different estimate, and strongly supported in such an estimate by high medical authorities. No one will deny, too, the special authority of Sir William Roberts in such a question. At the same time, we are bound to say that there is need for more specific facts on the side of those who tell us that a lower death-rate obtains among the nations that drink hardest. Sir William Roberts himself said, and with obvious truth, that such a statement was not tantamount to saying that the high drinking-rate and low death-rate were to be regarded as cause and effect. Have we any proof that alcohol saves men from any specific form of disease? Some say that it tends to save from tubercular disease; some from cancer; some from infectious diseases. There is a want of proof. But there are actual facts to show that coarse drinking favours death by consumption and death by cholera. And let it be remembered that it is the coarse drinking that characterises, according to Sir William, the nations with the low death-rate. As to the case of malignant disease, we do not recall for the moment any actual statistics. Is Sir William prepared to maintain that the western nations, to preserve their superiority, are to continue to drink in the old quantities? For it is the quantity that he associated in his address with the great results of health and history. We have a great deal of hard work to do before we can determine the *rôle* of alcohol in health and history. We have other great factors to consider—race, climate, sanitation, religion, and morals. Meantime let teetotal dogmatism take note of the weighed words of Sir William Roberts.

ENTERIC FEVER AND HÆMATURIA IN PIETERMARITZBURG.

IN his last annual report to the Pietermaritzburg Corporation, Dr. James F. Allen, the medical officer of health, enters at some length into two subjects of interest. The first is as to the connexion between enteric fever in man and a similar bovine disease. He has before pointed out that there was a disease in calves which resembled enteric fever, and which occurred at the same time of the year as that disease; that there has been a remarkable prevalence of enteric fever amongst cow and dairy keepers, and in the neighbourhood of cowsheds and dairies in Pietermaritzburg; that the disease tended to appear year after year in the dairies affected; and that it attacked those who used cow dung, either as a fuel or for the purpose of laying the earthen floors of their houses. He now quotes the opinion of one of the Government veterinary surgeons, which is largely in favour of the views he has expressed; and he reminds his readers that the description which is given of the calf complaint by this official coincides in almost every particular with that which applies to enteric fever. He next calls to mind the fact that, long before it was ever supposed that diseases such as enteric fever could in any way originate from bovine complaints, it was known that the fever followed the distribution of milk from special dairies, and that as precautions came gradually to be taken, which had for their object the prevention of milk contamination by any faulty sanitary circumstances in dairies, so the spread of disease from this source has been diminished. Such measures of dairy control are certainly needed to prevent the communication of bovine disease to man, and, since one of the ordinary regulations deals with the registration of dairies and the periodical inspection of cattle, their adoption in this and other countries should facilitate the investigation of such sources of danger as Dr. Allen refers to.

Another disease which has been the subject of inquiry is hæmaturia, which is common in the colony generally. Premising that the disease exceptionally attacks boys, Dr. Allen proceeds to give an account of the manner in which the Bilharzia hæmatobia, or other allied distoma or fluke, finds its way into the urinary tract. The children, he asserts, who resort for bathing purposes to the shallow pools of sluggish streams come into contact with the muddy deposits which are the natural habitat of the fluke. Dr. Bilharz noted the existence of the parasite amongst the inhabitants of the Nile Valley, and he believed it got into the body in unfiltered drinking water, and so into the vascular system. Dr. Allen, dealing solely with the facts that come under his own observation, holds that the history of the conditions is entirely at variance with the theory of the vascular system being the habitat of the parasite in the human body. He first asserts that those who bathe are the main sufferers; that swimmers resorting to deep waters are not amongst those mainly affected; and that drinkers of water are not especially attacked unless they are bathers too. And he further alleges that, the breeding beds of the fluke being disturbed by boy wadera, the sack-like receptacle of the prepuce in early life forms a place to which the flukes would readily have access, and in which they would be easily retained until they could enter the opening of the urethra. Indeed he suggests that the presence of the fluke in the waters of the Nile was one of the reasons for the operation of circumcision; and he adds that in certain parts of Africa where the fluke exists circumcision is or has been practised—as, for example, among the Basutos. That practice, he believes, will again have to be generally adopted in a country where bathing is an essential to comfort, if the prevailing hæmaturia, so general a cause of debility in the colony, is to be prevented.

FRENCH MEDICAL ASSOCIATIONS AND MUNICIPAL APPOINTMENTS.

FRENCH provincial medical associations are more apt to take cognisance of alleged breaches of professional etiquette by their members than similar societies in this country. This is as it should be, always supposing that the decrees of censure or expulsion are only pronounced after a careful and unbiassed investigation of the circumstances. Two cases have recently occurred in the Ain Association, which have been the subject of considerable discussion in local journals. In Bourg, the municipal medical inspector of prostitutes having died, the mayor appointed a Dr. X. to act in his place. After nearly a year the municipal functionaries were changed, a different party getting into power, and Dr. X. was, without much loss of time, superseded by Dr. Z., whose political views were in accordance with those of the new corporation. Dr. X. complained to the Medical Association, and notwithstanding the plea of Dr. Z. that he had in no way sought the appointment, and that Dr. X. was only appointed temporarily as acting inspector, the Association, or rather twenty-nine out of the eighty-one members of it, decided to expel Dr. Z. Again, the infirmary authorities of the town of Beliey, after a change in which a fresh political party came to the front, decided to dismiss their two medical officers, MM. A. and B., appointing in their places two gentlemen, MM. X. and Z., whose political views were more in accord with their own. Here the event gave rise to highly polemical discussions in the local press, party feeling running very high. The Medical Association, however, expressed its opinion of the matter by expelling MM. X. and Z. for having made their political views a means of supplanting their *confrères*. In commenting on this matter, a French medical journal remarks that in most

Digitized by Google

provincial towns medical appointments are given, as a rule, to the practitioner of the oldest standing, and that in this way they all tend to accumulate in the hands of the same man, with an entire absence of regard to his fitness for any of them. There are, too, a number of appointments given by interest, often to very unsuitable persons, who unfortunately, as a rule, have a prescriptive right to them for life. So that there is a curious contrast between appointments decided by public competition, which are nearly always limited in tenure, and those given by interest, which can be held for life. The writer of the article referred to holds very strongly that all appointments should be given by competition, but he does not indicate how anything like a satisfactory competitive examination or oration could be conducted in a country town every time such an appointment as that of medical officer to the local infirmary or fire brigade happened to be vacant. One thing is very plain, and that is that our system of the Poor-law Board's sanction being required for any change in the medical and other appointments might with advantage be considered, if not actually copied, in France.

COMMUNICABILITY OF DISEASE FROM ANIMALS TO MAN.

THE transmission from the cow to man of scarlet fever and tuberculosis was the subject of the opening address of Professor Hamilton at Marischal College, Aberdeen, in which the lecturer gave an excellent account of the investigations conducted by Mr. Power and Dr. Klein into the relation of a cow malady to scarlet fever in man. He referred also to the observations of Copland, who believed that both the dog and the horse could suffer from the latter affection, and stated that a febrile condition of some kind can be communicated to animals by inoculating them with the blood of persons who are the subjects of scarlet fever. He further expressed the opinion that tubercle could be conveyed to man by means of milk from tuberculous cows. While the possibility of such occurrence cannot be denied, it must be borne in mind that Klein has pointed out that there are certain important differences between bovine and human tuberculosis; and again, Creighton has shown that man occasionally suffers from a form of this disease which resembles the bovine malady, making it probable that by far the greater number of cases are not of bovine origin. Nevertheless, the subject deserves much greater investigation, and certainly every effort should be made to prevent the distribution of milk from tuberculous cows.

SICK BENEFITS IN GERMANY.

IT is well known that the German Government, which much affects vast insurance schemes, has formed sick benefit funds under a comprehensive plan in all parts of the Empire. The benefits guaranteed comprise free medical attendance, payment of wages during illness, and burial money, and membership is made compulsory upon the industrial classes. The system, which did not at first work at all smoothly, is coming, it would seem, into better repute with the people generally; but we imagine that its results in actual work will be somewhat disappointing to its promoters. The following illustrative figures, which have appeared in a report made by the United States' Consul at Leipsic, are interesting under this point of view:—The influence of the system on the relief of the poor is shown by the statistics of Hamburg. The cost of the sick poor who would have been cared for out of the poor rates in Hamburg in 1885, taking the average of the four preceding years, would have been 293,223 days of sickness at 1m. and 34,464 at 75 pfennings; the actual numbers were only 230,123 and 34,254. The saving in this decrease is estimated at 66,257m., or a net saving of 21,673m. The figures of the Leipsig City Hospital lead to a similar result. The cost of treatment chargeable to the poor rate, which was 51 per cent. in 1884, was only 39 per cent. in 1885, and simultaneously the proportion borne by public or private sick funds under the law rose from 8 to 24 per cent. The total number of persons insured under the Act is 4,294,173, or 91·7 per 1000 of the population. In itself admirable, the result does not seem commensurate to the efforts made to achieve it. For example, who among ourselves would have paid any attention whatever to Canon Blackley's scheme of National Insurance if, instead of promising to abolish poor rates, it had promised only to reduce them by 15 per cent, and this at a cost of coercion on a vast scale? The efficient tendance and relief of the sick poor is only a very partially solved problem among ourselves; but the experience of Germany so far does not incline us much to the adoption of the German methods.

THE SALE OF DAMAGED FOOD.

No argument should be needed to impress the fact that food, however simple in kind, must, if it is to fulfil its purpose, be of sound and nutritious quality. Alike with a view to the performance of work and the prevention of disease, the daily bread of poor as well as rich must be such as to satisfy this primary condition; and it is happily one of the certain benefits conferred by free trade that a greatly increased importation of the necessaries of life has done away with every excuse for the fraudulent sale of damaged food. There is, however, a temptation bred of the very abundance of an overflowing market and the competition in trade, which is its outcome, and of this we have daily proof in the seizures of unsaleable fish, fruit, &c., effected by the sanitary authorities. Of the economic side of the question generally we will say nothing; but when we find food which, as lost merchandise, has lain in the ooze of the Thames, recovered and offered for sale, as happened a few days ago, and when substances putrid with decay are successfully foisted upon an unthinking population, we feel that it is time to speak a word for the economy of health. Sanitary inspectors have repeatedly shown a praiseworthy zeal in condemning the wares of unscrupulous salesmen, and have, as a rule, been supported by a judicious application of the law on this subject. It is, however, neither advisable nor requisite that the whole task of detection and exposure should fall to the lot of any body of officials, however efficient. The consumer can, in matters of this kind, do much to protect himself. It is for him to be careful in his purchases, and the more so in proportion to the price which he is called upon to pay. It is, unfortunately, no uncommon thing to find that food of an altogether inferior and even injurious character is offered at the market value of a representative commodity, but it is naturally when the further attraction of cheapness is added that a customer's mistaken thrift is most likely to cost him dear. Fish, flesh, fowl, and vegetable, as supplied by many smaller purveyors, call for very careful selection on the part of a purchaser. He must therefore assure himself that the imported meat, which looks so well at a distance, has not lain too long on the butcher's hands since it was landed in a frozen state. He must remember that fruit, vegetables, and fish are still to be had in an unwholesome condition, though the summer season is over. In particular, we would warn him of the sealed mischiefs which are apt to be enclosed within the covers of carelessly tinned meats and other eatables. The danger of putrefaction associated by many with the latter is not wholly imaginary. There is fortunately available, however, one sufficiently instructive sign of its presence—namely, the convexity of the metal ends, which invari-

Digitized by Google

ably results from the outward pressure of putrefactive gases. Allied to if not identical with this subject is that of illegal food adulteration, a form of fraud for the detection of which some technical skill is usually requisite. The protection of the public in this case must therefore largely depend upon the energy of official supervision, and we are happy to think that this power is in fairly active operation. Unfortunately, it has happened at times that vigour in securing conviction has not been adequate, and we are certain that an increased activity of the executive in this direction would not be misapplied.

EXPERIMENTS ON ANTIPYRETICS.

DR. H. A. HARE of the Pennsylvania University has recently published in the *Therapeutic Gazette* (July and August) details of an experimental inquiry upon the action of antifebrin, salicylic acid, and carbolic acid upon animals, with reference to their effect upon normal and abnormal temperature, the concomitant changes in the circulation, and also to determine in what manner their influence is exerted. It will suffice here to reproduce the conclusions arrived at, which are of considerable value. First as to *antifebrin*. This substance is found to produce marked depression of normal bodily temperature, with an occasional fall in arterial pressure. It is singular that antifebrin has but little power in reducing the pyrexia caused by the introduction of pepsin into the blood, which may depend on some organic changes produced by the digestive ferment. The drug reduces normal temperature apparently by influencing both production and dissipation, and in fever it acts by decreasing heat production. *Salicylic acid* slightly reduces normal bodily heat, but has very little influence over artificially induced pyrexia. It has no special influence upon the circulation, beyond a slight increase in arterial pressure, more marked in the normal than in the pyretic animal. In reducing normal temperature it probably acts on both production and dissipation, but it is uncertain and irregular in reducing high temperature, frequently failing to prevent an increase of bodily heat. *Carbolic acid* possesses considerable power in lowering normal bodily temperature, and possesses more influence over pyretic temperature than does salicylic acid. It probably decreases arterial pressure when lowering temperature, and very likely diminishes temperature by affecting both heat production and dissipation. These experiments, although of value in themselves, illustrate the difficulty in inferring therapeutical action from such observations. The type of fever produced in animals by pepsin can hardly be comparable to the pyrexia of disease; otherwise it is difficult to explain why the results above obtained do not wholly accord with clinical experience.

THE HEALTH OF RANGOON.

SOME interesting details concerning the health of Rangoon, Burmah, are to be found scattered in the recent Report on the Working of the Rangoon Municipality. Nineteen acres of land have been obtained for the purpose of erecting slaughterhouses. The mortality for 1886 was 26·6 per 1000. Of 1724 specified diseases, as many as 1240 were fatal attacks from "fever." Measures have now been adopted for providing Rangoon with a proper system of sewerage. No drainage, in its true sense, now exists. Every description of filth is thrown into holes by or beneath the houses, which are no longer built high off the ground, but stand on a damp subsoil, the emanations from which largely poison the air. As for sewage disposal, the river effects this, the deposits in the creeks being washed out by the tides. Since the report, containing extracts from those submitted by Dr. Pedley to his corporation, was issued, we learn that all the needed financial arrangements for the new system of sewerage have been completed, and that the specialities of the Shone system are to be utilised with a view of overcoming the difficulties which attach to the low-lying nature of the ground on which the greater part of Rangoon is built.

EXCAVATING MYELITIS.

HYDRO-MYELIA, syringo-myelia, and peri-ependymal myelitis are synonyms of the excavating myelitis on which MM. Joffroy and Orchard recently read a paper before the Academy of Sciences, Paris (*La France Médicale*, Oct. 11th, No. 119). In two cases which they examined they found evidence of a slow inflammation, and they consequently reject the view that the cavities result from enlargement of the central canal from cystic degeneration of a hæmorrhagic or gliomatous focus. These authors believe that the distribution of the vessels to the centre of the cord explains the anatomical disposition of the cavities. According to them, the course of events is first a myelitis affecting a special site in the neighbourhood of the ependyma, and this inflammation causes an obstruction of the vessels supplying the grey matter around the ependyma, and consequently there results a softening which proceeds to excavation. The formation of the limiting wall to the cavity follows, or is posterior to these alterations, and its pathogeny is therefore the same as that of the wall of ancient foci of cerebral hæmorrhage or softening. This interpretation differs from that of Grimm, who finds in the constitution of this vascular false budding membrane the characters of a tumour the origin of the whole process.

THE LATE EDWARD THRING, M.A.

THE death of the Rev. Edward Thring, who became head master of Uppingham School in 1853, is worthy of notice by us in relation to his courageous and well-remembered conduct in an epidemic of typhoid fever in 1875-76. The school numbered about twenty-five boys when he took charge of it; in his hands the numbers increased rapidly till they reached between three and four hundred. He might have doubled these numbers but that he considered that a head master ought to "know" his boys, and with greater numbers this knowledge would be difficult if not impossible. In the year 1875, during the autumn, a fever epidemic broke out in the town of Uppingham; from the town it spread to the school, and one or two fatal cases are recorded; on Nov. 2nd the school was obliged to disperse. The whole of the school houses and buildings went through a process of disinfection, and the sanitary arrangements were well looked after, and on Jan. 28th, 1876, the school met again. But the sanitary arrangements (drainage, &c.) of the town were so defective, and the fever had taken such hold of the place, that it was impossible to keep the school clear, and after three weeks several of the boys fell ill again. Now arose the question, "What was to be done?" The school could not be kept there, and it might be fatal to disperse it again. The only way out of the difficulty was to temporarily remove the establishment. On March 14th the school broke up for the Easter holidays. The masters went off to inspect different places on the Welsh coast, and, after many failures, they succeeded in finding a place suitable for their purpose. This place was Borth. There they found a good large hotel and a long row of nice houses forming a terrace from the station to the sea; of these they took entire possession. Ten days after, on March 22nd, a special goods train of eighteen trucks unloaded 300 bedsteads, with their bedding, on the Borth platform; the whole of the school furniture was removed, including even the contents of the gymnasium and library. The hotel stables were converted into the school carpentery and the coachhouse into a gymnasium, and a wooden schoolroom, 83 ft. by 20 ft., was erected in

Digitized by Google

the hotel grounds. On April 4th the boys assembled in their new quarters, and so the sojourn at Borth began. It was hoped that after the next Christmas holidays the school would be able to reassemble at Uppingham. Sir H. (then Dr.) Acland of Oxford undertook to inspect the sanitary condition of the town, and his judgment was submitted to the trustees of the school, who did not feel safe yet in recalling the school to Uppingham; indeed, they were not able to return until after the Easter holidays, which began on April 10th, 1877. During the stay at Borth in the autumn of 1876 a few cases of scarlet fever occurred; but by taking every precaution the disease was speedily stamped out. On the school leaving Borth, a large demonstration took place, at which some of the leading inhabitants made speeches expressing their sorrow that the school was going away, and their kind feeling of respect for Mr. Thring, the masters, and the scholars.

COLCHICUM IN GOUT.

WHETHER colchicum should or should not be administered is often a question of debate. Dr. Carter of Birmingham gives his own conclusions in the current number of the *Birmingham Medical Review*. He believes that this drug should be avoided in all cases attended with debility and cardiac feebleness, and that its use should be limited to early attacks of a sthenic type, and when the pulse is one of high tension. From the liability of colchicum to depress the system and to interfere with renal elimination, its administration should not be continued for a longer period than is absolutely necessary for the relief of pain. In order to prevent the employment of a larger quantity than is necessary for this purpose, it is desirable to give the drug in moderate doses, repeated at short intervals, rather than in a large single dose. He argues that there is no evidence of the curative influence of colchicum, and thinks, with many others, that, in spite of the relief afforded, it tends to favour recurrence, and that it is safer to avoid its use altogether if this is possible. We are disposed to admit the general soundness of these views; but the evidence in favour of colchicum promoting the development of gout is not entirely satisfactory. Dr. Carter's observations on colchicum as a vascular depressant are rational, and he has found that such dilators of arterioles as nitrite of amyl, nitro-glycerine and nitrite of sodium are scarcely inferior to colchicum in affording relief to gouty inflammations. Veratria, a powerful vascular depressant, is a principal constituent in a well-known nostrum for gout. Besides filling the cutaneous arterioles and swelling the skin, which actively perspires, with lowering of the general blood pressure, colchicum diminishes the function of the sensory nerves, and may in this way tend to relieve pain; the sweating may also aid elimination, and relieve the kidneys from some of their work.

FOREIGN COPYRIGHT.

THE law of foreign copyright has been greatly improved by the Convention which was last month ratified at Berne. By this treaty the authors of "books, pamphlets, and all other writings, dramatic or dramatico-musical works, musical compositions, with or without words, works of design, painting, sculpture and engraving, lithographs, illustrations, geographical charts, plans, sketches, and plastic works relative to geography, topography, architecture, or science in general—in fact, every production whatsoever in the literary, scientific, or artistic domain which can be published by any mode of impression or reproduction,"—will enjoy in respect of their works published in one of the countries now forming an International Union the same right in every other such country which the domestic laws give to native authors in respect of works published within the jurisdiction. Thus, the perplexities incidental to the multiplicity of treatises on the subject of copyright which have hitherto subsisted are replaced by the simplicity of one uniform system of reciprocal acknowledgment of the rights of authorship. One most important alteration which is thus made in the proceedings incidental to a claim of copyright is that it is no longer necessary for this purpose to register a book abroad. Compliance with the formalities required by the law of the country of original publication will be recognised throughout the Union, and a pitfall in the path of the unwary author has thus been effectually and securely closed. Another piece of good news for some among our readers is that the benefits of the Convention are to be extended to the authors of "all works which at the moment of its coming into force have not yet fallen into the public domain in the country of origin." This provision is, indeed, subject to a somewhat indefinite reservation of a right in each country to limit it by special agreement or domestic legislation. The contracting States are Great Britain, Germany, Belgium, Spain, France, Haiti, Italy, Liberia, Switzerland, and Tunis. Thus, the Union is a large one, and makes some important additions to the field open to meritorious authorship. But we still miss the name of the great Republic of the West. How long will our kinsfolk of the United States hold aloof from this act of literary justice?

THE LATE MR. C. R. BLAKISTON.

WE regret to record that Mr. C. R. Blakiston, the assistant house-surgeon at the Shrewsbury Infirmary, who was accidentally shot by his senior colleague, Mr. Harries, died on the 21st inst. from his injuries. After a hopeful day or two, symptoms of spinal meningitis as well as of peritoneal mischief set in, and he rapidly sank. Mr. Blakiston entered the Medical Department of King's College in 1881 as a preliminary science student, but after passing that examination did not proceed with the University course. He held many clinical appointments at King's College Hospital, including that of dresser and senior clerk to Sir Joseph Lister, Bart.; and he was a most able and intelligent surgeon. He was appointed assistant house-surgeon at the Salop Infirmary last year, and performed the duties of that office with great diligence and ability until his unfortunate accident. He was only twenty-four years of age, and his funeral took place at Shrewsbury General Cemetery on the 24th inst.

OPIUM-SMOKING IN CHINA.

IN Mr. Duncan Main's report of the Hangchow Hospital in connexion with the Church Missionary Society for last year, an analysis is given of the eighty-two cases of opium smokers which were treated. The great majority of these were from thirty to fifty years of age, only one being under twenty, and only two over sixty. They seem generally to have commenced the habit in the hope of gaining pleasure, but in a few cases they were impelled to begin smoking opium for the relief of pain. Some had continued the practice for fifteen or twenty years, but the majority only for from two to seven years. They belonged to all classes of society, the shopkeepers and commercial classes appearing to form the majority. In connexion with this subject Mr. Main says: "If those who are ever anxious to minimise and doubt the evil effects of opium smoking on the Chinese could spend a few days in the capital of Chekiang, we fancy they would rapidly come to the conclusion that of the physical ruin, harrowing scenes, beggary, and misery consequent on opium smoking the half has not been told." As to treatment, the opium is cut off absolutely; no routine system is followed with reference to drugs, but symptoms are treated on their merits. Plain food, a room with a lock and key, and kind words are half the cure. To give the patients liberty is a mistake, and to put

Digitized by Google

them on their honour is out of the question, as most of them lack all nobleness of mind. To allow them to roam about would mean a keeper for each patient, and he would certainly fail very frequently in his charge.

WORK AT THE HANGCHOW HOSPITAL.

EIGHTY-EIGHT cases of suicide, or attempted suicide, have been treated at this hospital. Opium was the favourite poison, and was used in eighty cases. Some tried mercury, arsenic, kerosine, oil, and salt. One young woman swallowed four gold rings, after cutting them into sixteen pieces. There was one case of hanging, and one of attempted cut throat. A very frequent disease in Hangchow is dyspepsia due to bolting half-boiled rice and vegetables and overloading the stomach. Amongst the list of operations those for entropium, trichiasis, pterygium, and other ophthalmic affections hold a prominent place. An attempt is made to train up students. Here, as elsewhere in China, the great difficulty of teaching anatomy, owing to the impossibllity of dissection, is felt. Thanks, however, to the Wm. C. Jones Fund, an admirable anatomical model, consisting of 2000 pieces, has been obtained, and with this "a very proficient" knowledge of anatomy has been acquired by the students.

LECTURES ON BACTERIOLOGY.

THE fact that the Society of Medical Officers of Health has had under consideration a proposal for the establishment of a laboratory for the study of bacteriology and other experimental methods of research amply testifies to the need there has been for a systematic course of instruction, and for a laboratory for research on this subject. It is only right, therefore, that it should be well known that this want has been supplied by King's College, and we may again draw attention to the fact that the new laboratory which has been constructed during the vacation will be open on November 1st for instruction and for original research. The course of instruction will be similar to that given in Berlin. Professor Crookshank will deliver about fifteen lectures, while the practical course under his direction will consist of daily work in the laboratory for a period of four weeks. The lectures will be given on Mondays, Tuesdays, Thursdays, and Fridays, at 10 A.M They will be illustrated with diagrams and typical preparations, and followed by practical work. Admission will also be given to the lectures without attending to the practical work. The College has thrown the laboratory open to all gentlemen, whether students of other departments of the College or not. The practical courses, in fact, are especially intended for medical officers of health, veterinary surgeons, and senior students, and we understand that special arrangements will be made with those whose duties may prevent their attending the laboratory daily without interruption.

FEVER IN LONDON.

THE number of cases of scarlet fever admitted into the Metropolitan Asylums Board hospitals during the week ending Oct. 21st amounted to 275, being two less than that admitted in the preceding week. Thus far the behaviour of the epidemic has followed the course which might be predicted by the experience of former years. November should show a general decline with a temporary rise, and December a steady decline from the beginning to the end of the month, the average number of cases for the whole year being reached in January. The returns up to 10 o'clock on Wednesday state that during that night there were in the hospitals 2450 patients. On the morning of that day there were 2270 suffering from scarlet fever, and 123 from enteric fever. During the past week 11 cases of enteric fever were admitted into these institutions; all the cases but two occurred in different districts, and one person suffering from small-pox was admitted from Whitechapel. The last was a child aged four years, in whom the condition as to vaccination is not stated.

THE NIGHTINGALE FUND.

FROM the report of the fund of the Nightingale Home, or School for the Training of Nurses, at St. Thomas's Hospital, for the year 1886, it appears there were forty-seven probationer nurses admitted during the year, making, with those remaining from 1885, seventy-eight who received instruction. Of those admitted during the year twenty-three resigned, or were discharged as unsuitable for the work. Ten lady probationers and sixteen nurse probationers were entered in the Register as certified nurses after satisfactorily completing their year of training. After an account of the various appointments obtained by certified nurses, an acknowledgment to medical lecturers and others for their services, and a statement of the branch of the home at St. Marylebone Infirmary, reference is made to the retirement of Mrs. Wardroper from the post of superintendent, which she had held since the formation of the school in 1860. A slight sketch of the history of the Nightingale Home is given, and a strong expression of feeling as to the great importance of the labours of the matron and superintendent during that time, so much of the success being due to her energy and management. Mention is made of the numerous places, not only in England, but throughout the world, to which nurses have been sent. The abstract of accounts shows a balance in hand of £1736 16*s*. Amongst the more serious items of expenditure are—expenses of training hospital nurses at St. Thomas's Hospital, £1439; contribution to expenses of Training School at St. Marylebone Infirmary, £153 5*s*. 6*d*. From this report it is impossible to do otherwise than come to the conclusion that this Nursing Home has done a very great amount of good work during the time that it has been in existence, but it is a question whether its field ought not to be extended, and an offshoot established of trained nurses, whose services should be obtainable for work amongst the upper and middle classes. This has worked well in connexion with other large London hospitals.

POISONING BY FISH.

A SPANISH naval surgeon, Señor Don Antonio Jurado y Calero, writing in a recent number of the *Boletin de Medicina Naval*, describes the serious effects observed on board his ship, the gunboat *Magallanes*, from eating fish caught in the Bay of Buena Esperanza on the south coast of Cuba. No less than twenty-seven of the officers and crew were affected, most of them with gastro-intestinal disturbance of a more or less severe nature, the others with nervous symptoms. Those of the first group presented nausea, persistent vomiting and diarrhœa, followed by coldness of the extremities, small and contracted pulse, and in some cases rigors; afterwards a febrile condition supervened. The men were nearly all able to return to duty within two days. They complained, however, for some time afterwards of irritation of the skin. In the more severe cases there were dilatation of the pupils, marked diminution of sensibility, complete anuria from spasmodic closure of the sphincter of the bladder, and in some cases convulsive movements of the muscles. Those whose symptoms were purely nervous were not attacked till some time later than those forming the first group, and they suffered much less severely, complaining chiefly of cutaneous irritation and headache, also of sleeplessness, which last continued more or less for three or four weeks. In both forms of the affection the termination was accompanied by a cutaneous eruption like urticaria, or in some cases by the appearance of a number of

Digitized by Google

pustules on the skin. This, the author thinks, indicates that the proper treatment for poisoning by fish is to act on the skin. Besides, therefore, combating the gastro-intestinal and nervous symptoms with opiates, bromide, &c., he endeavoured to produce diaphoresis by giving lumps of sugar containing twelve or fourteen drops of sulphuric ether, and exhibited an antispasmodic mixture consisting of syrup of orange, lime-flower and orange-flower water, and sulphuric ether. He also allowed the patients to drink hot tea freely.

THE PROGNOSIS IN ALBUMINURIC RETINITIS.

AN interesting discussion was raised as a digression at the last meeting of the Ophthalmological Society on the subject of the prognosis of albuminuric retinitis. Dr. Angel Money, who gave the turn to the discussion, said that in his experience the average duration of life was to be measured by months. This view was supported by Dr. J. Anderson, who had instituted an inquiry in the matter, and came to the conclusion that the longest duration was thirteen months and the average six months. Dr. Stephen Mackenzie did not contest the main issue, but narrated some cases which went to show that life might be prolonged even for years. Indeed, he mentioned one case in which considerable progress towards recovery took place, so that after a time the ophthalmoscopic changes were not very noticeable. Mr. Marcus Gunn agreed with the view that the duration of life was not usually long. Mr. Nettleship considered that if the changes in the eyes were associated with renal disease and pregnancy, then, provided a safe delivery was accomplished, the prognosis was much more favourable than in ordinary cases. Mr. McHardy had seen a case in which the patient lived for many years after the detection of the albuminuric retinitis. Dr. W. J. Collins thought the prognosis more favourable when mere hæmorrhages existed, but less hopeful if other retinal changes had developed.

SMALL-POX ISOLATION AT PERTH.

THE Local Authority of Perth having noted the grounds on which the infirmary directors decided to deal with small-pox in their own institution, and having heard the rejoinder of Dr. Simpson, who protested against such use of a general infirmary in the interests of public health, have decided to send the reports on the subject to the Board of Supervision. Another infirmary nurse has contracted the disease, but all the patients have been revaccinated.

PROPOSED INTERNATIONAL MEASURES AGAINST ADULTERATION.

AMONG the many practical advantages arising from the International Congress of Hygiene recently held at Vienna, we should mention the very active campaign carried forward on an international basis against food adulteration. This grave question was first brought forward by Dr. Brouardel at the Geneva Congress in 1882. He then showed how long it took to discover first the existence of adulteration, and secondly some practical means of easily detecting its presence. Then the law had to be moved in the matter, and often that required more work and time than all the other parts of the process. Meanwhile manufacturers who had able chemists in their service discovered some totally different method of adulteration than that hitherto in vogue, or else simply crossed the neighbouring frontier and there found a law and methods of analysis not conceived for the purpose of checking their particular method of fraud. Thus, under a different government the old practices of adulteration could be commenced over again. Dr. Brouardel strongly urged the necessity of assimilating as far as possible the legislation of all nations on this matter. At the Congress of the Hague, in 1884, it was decided that inquiries should be made as to the law against adulteration in all countries, and consequently for the Vienna Congress Dr. Brouardel was able to present a report giving the result of this investigation. We have thus before us a summary of the laws and decrees against adulteration enacted in Germany, Bavaria, Prussia, England, Austria, Hungary, Belgium, France, Italy, the Turin municipal bye-law, Portugal, municipal law of Lisbon, Roumania, Servia, Sweden, Norway, the separate laws of the twenty-two cantons of Switzerland, and of Canada. The list, it will be seen, is not complete; from Russia, notably, in consequence of complex local legislation, nothing could be obtained. Still, the material collected is international enough, at least for a beginning. It demonstrates unfortunately a considerable inequality of the law in different countries; but, on the other hand, it also shows a general desire to cope with the evil. The first great difficulty is the definition of terms. "Falsification" or "adulteration" is defined in so many ways that, till all parties can agree to give, in all languages, the same meaning to the same word, it will be impossible to proceed in a uniform manner against the abuse the word represents. Nevertheless, and however great the obstacles may be, the problem has to be faced. As we consent to increase the facilities of international intercourse and are ever seeking to interchange the products of different countries, we can no longer remain indifferent as to the laws enforced by our neighbours. If we eat American ham and French butter, we want to know what method of *surveillance* is adopted in those countries to protect us from trichinosis in the former, or from injurious colouring matter in the latter. If we export cotton goods and other wearing apparel, foreign nations have a right to inquire what measures we take to prevent the colouring of these tissues with materials that may produce irritation and sometimes serious disorders of the skin. M. Brouardel's paper was followed by papers from Professor Gabriel Pouchet of Paris, Dr. Angelo Caro of Madrid, Dr. Ferrière of Switzerland, Dr. A. Hilger of Erlangen, and Dr. Hamel Roos of Amsterdam. The cause is therefore well before Europe; and doubtless many opportunities will arise of dealing with the details, as from day to day various grievances are brought to light.

OXFORD WATER SUPPLY.

FOR many years the Oxford water supply was under suspicion, and this both on account of its quantity and by reason of the existence of a cesspool district in immediate proximity to the storage lake. The latter evil has, we believe, been altogether done away with, and now an addition to the service has been made, which will provide the town with four million gallons a day drawn from a spot in the Thames some miles above Oxford. Sir Henry Acland, at the inauguration of the works, contrasted the unsatisfactory state of Oxford forty years ago with that which now prevailed in regard to water service.

VARIATIONS OF VITAL CAPACITY.

DR. THEODOROFF presents, in the form of a graduation thesis, in St. Petersburg, a laborious set of observations on the influence of the time of day upon the vital capacity of the lungs, and on the force of inspiration and expiration. His material consisted of ninety-six healthy men from Livadia, whom he examined twice a day for several consecutive days, and of fifteen individuals belonging to a different locality, whom he examined nine times a day for some time. The instruments used were Hutchinson's spirometer, and Waldenburg's pneumatometer. He found that the vital capacity increases from morning till evening, decreasing again during the night. After each meal, too, there is a special

Digitized by Google

increase, followed by a slight decrease; the vital capacity being at its highest shortly after dinner, and at its lowest after getting up in the morning. Thus, from a diagram giving average results, we find the numbers as follows (in cubic centimetres): 8 A.M., 3550; 9 A.M. (after morning tea), 3615; 11 A.M., 3605; 12 noon (after breakfast), 3623; 5 P.M., 3618; 6 P.M. (after dinner), 3631; 9 P.M., 3610; 10 P.M. (after evening tea), 3615. The force of inspiration and expiration follows nearly the same law, the main exception being that evening tea has no effect on the former, and only a slight one on the latter.

THE NEW ENTRIES.

THE following is the number of the students who have entered at the various medical schools which were not included in the list we published last week:—

	Entire course.	Special classes.	Prelim. Scien.
St. Bartholomew's Hospital	140	18	—
Charing-cross Hospital	65	28*	—
St. George's	34	3†	1
Guy's	64	16	15
St. Mary's Hospital	69	30‡	16
Westminster Hospital	20	5†	—
Bristol School of Medicine	22	2	—
Queen's College, Birmingham	40	21‡	9
Yorkshire College, Leeds	41	5	—

* Including 16 dental. † Including 1 dental. ‡ Including 2 dental.

THE NOTIFICATION OF INFECTIOUS DISEASES.

WITH a single dissentient the Metropolitan Asylums Board have passed a resolution urging the Local Government Board to take the necessary steps for the extension to the metropolis of the system of compulsory notification of infectious diseases. The same subject also continues to be discussed in the general press, and Dr. Tomkins, medical officer of health for Leicester, states that eight years' experience there has served fully to disprove the allegations made against the system, and, above all, that relating to a supposed difficulty between patient and doctor owing to so-called violation of confidential relationship. We have so recently expressed our views as to whether the present time is an opportune one or not for further pressing the system by means of any legislative enactment, that we need not refer to the subject further on this occasion.

THE PROTECTION OF LEICESTER BY VACCINATION.

IT is important to fix rightly the responsibility of the state of Leicester. This rests on the guardians, who, by an absurd confusion of duties, are charged with the administration of the Vaccination Acts. *They* are the blind leaders of the blind, and not the sanitary authorities proper.

ADENOID TUMOURS OF THE PHARYNX.

MANY are the evils attributed to the presence of overgrowths of adenoid tissue in the naso-pharynx. They are believed to cause reflex neuroses, to set up various local morbid conditions, to predispose to other diseases, and generally to play such *rôles* as to lead to the conclusion that their existence is very undesirable. M. Coupard believes that in a large number of individuals, especially infants, a simple catarrhal laryngitis takes on a spasmodic character as the result of the anterior existence of adenoid vegetations in the naso-pharynx. And he further opines that many cases of stridulous laryngitis attended with the nocturnal paroxysms of suffocation are due to the presence of adenoid vegetations in the pharynx. These tumours, it is urged, should be removed, for their mere presence entails a chronic catarrh, with difficulty of breathing through the nose, great liability to deafness and aural disease, as well as to the occurrence of other symptoms definite enough in any particular case. Their effects may be fully as injurious, and are in some respects like those due to mere enlargement of the tonsils.

SIR WILLIAM GULL.

OUR readers will be glad to learn that Sir William Gull continues to maintain his ground, and improvement in his power is perceptible. His appetite is fair, he sleeps well, and his spirits are good. He has no secondary trouble or complication. Kind messages of inquiry and sympathy are still kept from him. The following bulletin has been sent to us for publication:—

Sir William Gull continues to make satisfactory progress. He sleeps fairly well; there is little or no rise of temperature, and the power of motion has in a large measure returned. On Monday he was moved in a chair to a larger and brighter room, and seems much benefited by the change.

(Signed) ROBERT IRVINE, M.B.
Urrard House, Pitlochrie, Oct. 26th, 1887. T. D. ACLAND, M.D.

ANIMAL AND VEGETABLE DIETS COMPARED.

DR. BAFTALOVSKI having secured the intelligent co-operation of four medical friends, proceeded to diet them and examine their secretions, in order to obtain information as to the different effects produced by various classes of food on the human organism. With purely animal diet the mean assimilation was 95 per cent., and the nitrogenous metabolism 108·6 per cent.; the extractive matters in the urine being more than when the diet was exclusively vegetable. With vegetable diet the assimilation was 42·5 per cent., the nitrogenous metabolism much less than with animal food, and the extractive matter four times as great as with a mixed diet. With a mixed animal and vegetable diet the assimilation was nearly as high as with the exclusively animal food, being 92·4 per cent.; but the metabolism was considerably less than with animal, but more than with vegetable, food.

OPHTHALMOLOGICAL SOCIETY'S LIBRARY.

THE Ophthalmological Society may be congratulated on the promptitude with which the nucleus of a good library has been formed. A catalogue of the library has been completed, and was presented at the ordinary meeting of the Society last week. Copies of the catalogue may be obtained at the price of one shilling at the Medical Society's rooms in Chandos-street. Already there are nine hundred volumes in the bookcases and on the shelves. All the important ophthalmic periodicals, both English and foreign, are subscribed for by the Society, and the library is probably the best in London for ophthalmoscopic works.

THE SANITARY ASSOCIATION OF SCOTLAND.

THIS Association have held their tenth annual meeting at Falkirk, a town in which, according to ex-Baillie Griffiths, who welcomed them in the name of the magistrates and Town Council, sanitation may be seen in some of its worst forms. Mr. G. D. Mackay gave the presidential address on "Helps and Hindrances to Sanitation," and he was followed by Dr. M'Vail, who complained that the new Scotch Act failed to meet the needs of Scotland. In the first place, as its very name indicates, it applies essentially to burghs and towns, whereas in such matters as enteric fever, scarlet fever, and tubercle, the source of the mischief often lies many miles away in rural farms and dairies. Then, again, it makes no provision for a staff of skilled medical inspectors,

Digitized by Google

such as are attached to the central authority in England, and whose work, Dr. M'Vail declared, was widely known amongst all sanitarians. In short, it was felt by the Association that such an Act could only be regarded as a stop-gap, and that it must be supplemented by some more complete and efficient measure.

DISTILLATION OF WATER AT THE AMERICAN EXHIBITION.

AMONG the exhibits at the American Exhibition was an apparatus for the distillation of water, the property of the Hygeia Water Company of New York. The water is first distilled and subsequently aerated, so as to give a little more agreeable taste than is proper to mere pure distilled water. Care is taken, by Professor Tyndall's method, to deprive the air so used of all micro-organisms and other impurities; and some method is also used to destroy such elements in the water itself previously to distillation. The result is a very pure water, which is said to be extensively used in New York in the manufacture of mineral waters &c., and to be very much recommended by the medical faculty there. Of course, our great water supplies should be so pure as to make us independent of particular methods of distillation for ordinary drinking purposes. Would they were so. Meantime an apparatus such as that noticed above is highly important and of great public value.

AXILLARY ADENITIS.

IT is believed by M. Grancher that tubercular diseases of the lungs may through the mediation of the pleura infect the ganglia of the axilla. This peculiarity does not appear hitherto to have attracted much attention, and it is thought that the occurrence of such axillary adenitis may not be rare. The knowledge of these facts is regarded as having much importance, not only from a doctrinal point of view, but also from the standpoint of diagnosis; and M. Grancher advises that henceforth every case of phthisis should be examined for axillary swellings, and, conversely, that every case of axillary adenitis should be examined for the signs of pulmonary mischief.

DIPHTHERIA PREVALENCES.

DIPHTHERIA is prevalent in the village of Tiverton, Cheshire, and also at Thirkleby, near Thirsk. The outbreak in the latter place is a serious one, and it has locally been attributed to the unsatisfactory condition of fold-yards. The subject is worth further investigation, for in numerous instances the association of diphtheria prevalences with conditions under which animals are kept has received some prominence.

ST. PETERSBURG PASTEUR INSTITUTE.

ACCORDING to a report issued by the St. Petersburg Institute for Antihydrophobic Inoculations on the Pasteur system for the first year of its existence—i.e., from July 1886 to July 1887—266 persons have been treated there, 126 being inhabitants of St. Petersburg. From this number 20 must be deducted, comprising those still under treatment, those who did not remain for the completion of the treatment, and those whose wounds were proved to have been inflicted by non-rabid animals. Of the remaining 246 (98 males and 58 females) 7 died. Of those living, 148 had been inoculated more than six months, and 60 more than three months, previously to the issuing of the report.

FOREIGN UNIVERSITY INTELLIGENCE.

Brussels.—At the opening of the session which has just commenced, the ceremony in connexion with which took place at the Hôtel de Ville under the presidency of M. Buls, the Mayor, the Administratem read a report announcing a considerable increase in the number of students. Subsequently, M. Depaire gave a lecture on the more recent applications of Spectral Analysis and the Composition of the Heavenly Bodies.

Prague (Bohemian University).—Dr. J. Hlava has been promoted to the rank of Professor of Anatomy.

THE first number of the *New Zealand Medical Journal*, published in September, has just reached us. It contains some sixty pages of very readable and professionally valuable matter, and a systematic arrangement of the contents of future numbers is promised. The journal is to be published quarterly, the subscription being 10*s.* per annum.

THE Secretary of St. George's Hospital has not yet received official information of the fact that £100,000 has been bequeathed to that institution by the late Mr. M'Calmont, but is of opinion that there is no reason to doubt that the bequest has been made, having been told it on the authority of one of the executors.

IT is announced that for the season the P. & O. steamers will call every week at Gibraltar for Morocco, Granada, Seville, and south of Spain, thus enabling invalid and other passengers who intend wintering in the south of Europe to avoid the long railway journey to those places.

A BILL relating to compulsory vaccination and revaccination will, it is stated, shortly be laid before the Austrian Reichsrath. It is proposed that all children should be vaccinated twice, at the ages of one and twelve.

THE Special Board for Medicine at Cambridge University have elected Dr. Humphry, Professor of Surgery, a member of the General Board of Studies till Dec. 1st, 1890, in the place of Professor Sir G. E. Paget resigned.

Pharmacology and Therapeutics.

DELPHININE.

THE plant Delphinium staphisagria yields, according to M. Vincent Gauthier, four alkaloids, of which the chief one delphinine, occurs as an amorphous powder of yellowish colour and resinous aspect, and having the chemical formula $C_{22}H_{35}NO_6$. It is insoluble in water; dissolves in alcohol, ether, chloroform, and acidulated water. The parts of the plant usually employed therapeutically are the seeds, which contain the great part of the active principles. The seeds have for a long time been employed against psoriasis, and as a vermifuge in the form of powder, decoction, ointment, or infusion. Delphinine is preferably administered in the form of granules or small pills, and the dose should not exceed from 1 to 10 milligrammes a day. Delphinine acts chiefly on the nervous system, and first upon the bulb, next upon the sympathetic. It produces at first a functional excitation, then, by graduated attenuation, a diminution and complete but transient abolition of sensation. The analgesia may, however, persist for twenty-four hours. In order to produce these effects, it acts directly upon the central substance of the nerves. This physiological action on the sensibility of the body is the most important property, and the only one of a therapeutical value. It is said to be preferable to aconitine, because it is so much less toxic. On the motor nerves delphinine has no action in physiological doses, but in toxic quantity the functions of these motor nerves are entirely abolished. Delphinine acts upon the locomotor system, causing incoördination with ataxia, but the contractility of the muscular fibres persists till somatic death. The alkaloid acts also on the heart and sanguiniferous circulation, accelerating the cardiac movements at first, and disturbing the rhythm. Then follows a period characterised by regular

Digitized by Google

rhythmical contractions of a large and ample kind. Finally the heart is arrested in diastole. This action of the delphinine is effected through the medium of the bulb and pneumogastric nerves. The variations of the blood tension consist in a transient elevation, followed by an abatement, which becomes more and more marked. Delphinine also affects the respiratory functions, causing a true arrhythmia of the respiratory movements effected by the abdominal, intercostal and diaphragmatic muscles. The respiratory arrhythmia causes an augmentation of the carbonic acid in the blood. When the tetanic spasm has attained its maximum, the lung no longer acts and the animal succumbs from the consequent asphyxia. Delphinine may produce vomiting and diarrhœa. The pupils are first contracted, and afterwards dilated by it. The salivary, biliary, urinary, and intestinal secretions are all increased. In the treatment of poisoning by delphinine artificial respiration occupies the chief place, and this is done to afford time for the elimination of the poison. There is a partial antagonism between strychnine, which affects the sensation differently, and between atropine, which has an opposite effect on the heart, but neither strychnine nor atropine can prevent death by delphinine, unless artificial respiration is practised. The physiological effects of delphinine on the sensitivity of the body indicate its therapeutical employment in cases of neuralgia, and in other diseases attended with hyperæsthesia, as in neuralgia of the trigeminal. As to the mode of administration, the internal employment is preferable to subcutaneous injection on account of the insolubility of delphinine in water. The maximal dose should be one milligramme, repeated every two hours until some of the desired effect is produced. External application can have but little effect, partly because so little is absorbed, and partly because delphinine must produce its effects by acting on the bulb.

MORRHUOL.

There has just been published in Paris by G. Steinheil an interesting clinical study upon Le Morrhuol, the extract of cod-liver oil, by E. Chazeaud, and the chief conclusions at which he has arrived are as follows: Clinical observation has demonstrated in a conclusive fashion the high therapeutical value of morrhuol. It increases the appetite and regulates the digestive functions, increases rapidly the weight of the body, and leads to positive *embonpoint*. The urea discharged in the urine is also augmented. The cough is diminished and finally extinguished, whilst the debility disappears. These excellent results are not confined to cases treated at hospitals, but cases in private practice are equally benefited. Besides tuberculosis, anæmia, rickets, and scrofula (lymphatism) are equally amenable to its beneficent influence. The small size of the morrhuol capsules enables them to be taken with ease by the patient, and nausea and diarrhœa are also prevented. To so many advantages one slight disadvantage must be added, but even this is of rare occurrence—it is the development of acneform spots similar to those produced by iodides. The number of capsules to be taken varies in different cases from two to eight per day, and eight capsules are equivalent to forty grammes of brown cod-liver oil.

HÆMOSTATIC ACTION OF ANTIPYRIN.

Dr. Olikoff writes to the *Russkaya Meditzina* that, having seen in some medical journal that antipyrin possesses hæmostatic properties, he made use of a solution of ninety grains in six ounces of water for inhalation in six cases of hæmoptysis. He ordered five or six inspirations to be taken through the inhaler every half hour or hour. This had the effect of diminishing the hæmoptysis at once, and of rapidly arresting it.

INFUSION OF DIGITALIS.

A Utrecht military pharmacist, writing on the preparation of the infusion of digitalis in the *Nieuw Tydschrift Voor Pharmacie in Nederland*, recommends that only the parenchyma of the leaf should be employed, which, he says, contains about 1 per cent. of digitaline, while the stalks and nerves of the leaves contain only about 0·02 per cent.; the latter also tend to make the infusion gelatinous.

SALOL IN SCIATICA.

Dr. Aschenbach has found that salol taken internally relieves his sciatica better than any other remedy. He first took seven grains and a half, and later on the same day fifteen grains.

HEATSTROKE.

THE following is a report of the discussion that followed the reading of Mr. Anderson's paper, which appears on p. 856.

Dr. E. A. WOOD (Pittsburg, Pa.) said that while the different pathological conditions of sunstroke are important, yet the all-important pathological fact to be considered is the exalted temperature. We find a weak circulation—stimulants will not strengthen it; convulsions—hypodermic injections of morphia may arrest them; a stomach loaded with undigested food—the stomach pump will empty that stomach, and aperients may empty the bowels; and yet when all these things are done the patient is still unconscious, because the great and all-important factor is still there. The rapid oxidisation of the tissues is measured by the thermometer. Now if we begin at the other end and succeed in reducing the temperature, to its near normal standard, neurotic conditions, debility, unconsciousness, and indigestion rapidly right themselves. The all-absorbing consideration in cases of sunstroke is to reduce the abnormally high temperature, and until that is accomplished no other matter is worth regarding. This must be done quickly if we wish (first) to save life, and (second) to prevent unpleasant and lasting consequences to the nervous centres. Common sense would naturally turn to the external application of cold, and that treatment has become universal. Every stitch of clothing should be removed, cold water dashed over the body, ice applied, even ice in the rectum, and one or two assistants should vigorously employ fans to cause greater coldness by rapid evaporations. Dr. Wood was partial to one single hypodermic injection of fifteen grains of antifebrin, as being more rapid and more intense in its effects than quinine.

Dr. W. H. LLOYD (London) confirmed Dr. Anderson's views as to the efficacy of temperate living and good ventilation as prophylactics in the avoidance of heat apoplexy. Heatstroke is not ordinarily a frequent disease in the British navy, but 90 per cent. of these cases occur in the Red Sea in ships passing through the excessively high temperature usual in this region at certain seasons. These cases are, almost without exception, in the persons of cooks, saloon stewards and bakers, and occasionally stokers; rarely is a blue-jacket or a man working on deck a victim. The classes mentioned generally spend much of their time in close, ill-ventillated places, and are often addicted to unwholesome living and alcoholic excess. They are generally a flabby and etiolated class, and are rarely in a high condition of health.

Deputy Surgeon-General MARSTON, C.B. (London), concurred generally with Dr. Anderson and the previous speakers; he dwelt upon the distinction between heat exhaustion and heatstroke and heat apoplexy, which Dr. Anderson had very properly insisted upon. He related some of his experience in India, Egypt, and elsewhere, touched upon the causes and treatment, and especially called attention to the sequela and remote effects of sunstroke and exposure in hot climates—such as abnormal and erratic temperatures, insomnia, loss of "nerve," acute neuralgic headaches and other neuralgias, and occasionally, though rarely, even short attacks of mania. The nerves of special sense are also sometimes affected. Although forms of motor paralyses do occur, they are rare compared with the other forms of nerve lesion. Dr. Marston dwelt upon the importance of using a neutral soluble non-irritating form of quinine, as tetanus is liable to occur after slight punctured wounds and irritants, in hot climates, where there are great diurnal variations of temperatures.

Surgeon-Major LANGRIDGE, while in India, had some experience of the injection of neutral sulphate of quinine. His cases were not those of sunstroke, but were instances of very severe remittent fever accompanied by extremely high temperature. Ordinary remedies, including the administration of large doses of quinine internally, failed to reduce this to any extent. Hypodermic injections daily three or four times were then adopted with great success, and in no case was there a more severe symptom than the occurrence of a slight local induration.

Dr. ANDERSON, in reply to Dr. Wood's remarks, said that he regarded it as a matter of course that all means of reducing body heat, such as ice and cold affusion, would be adopted;

Digitized by Google

but he especially drew attention to the subcutaneous use of quinine, because it is the most powerful and rapid agent for this purpose with which he was acquainted. To antipyrin and antifebrin he had referred but very briefly, because he had no experience of these agents in these cases. Referring to the blood-letting spoken of by another speaker, he remarked that such practice was at one time very general in India, and the resulting mortality was so great that it was given up.

BRITISH MEDICAL BENEVOLENT FUND.

THE monthly committee meeting was held on Tuesday last at the house of the treasurer, Dr. Broadbent, and the resignation of Mr. Edward Newton, a member of the committee since April, 1880, was accepted with regret. There were fourteen cases before the committee, and a small balance only at their disposal. Four applications were passed over on account of the amount of income possessed by the applicants, or for some other cause, and three were postponed for further information, and grants, amounting in all to £83, varying from £2 to £18 were made to the remainder. A sum of £5, which had been advanced to a surgeon under circumstances of extreme urgency, after thorough investigation by a member of the committee, was repaid. In the case of an aged practitioner (seventy-one), to whom was voted £10 on consideration that £50 was subscribed privately for his benefit, this has not only been accomplished within the month, but an additional £10 or more has been subscribed, and the coming winter trials made comparatively light for a helpless paralytic, should he survive so long. The available balance was completely exhausted, and the committee is left with nothing in hand to meet the demands of November and December.

REPORT ON SANITARY MEASURES IN INDIA IN 1885-6,

TOGETHER WITH MISCELLANEOUS INFORMATION UP TO JUNE, 1887. (VOL. XIX.)

WE have so recently given, at considerable length, the details respecting the health of the European troops in India during 1885, that it is unnecessary to notice the section of the Report now before us relating to them. The average force of the native troops for the year was 115,486. The admissions into hospital were in the ratio of 978, the deaths of 16·09, and the daily sick, of 32 per 1000 of the strength. The admissions and mean sick were lower, but the deaths 3·87 per 1000 higher than in 1884. The sickness and mortality in the different divisions of the Army were as given in the subjoined table.

	Average strength.	Ratio per 1000 of strength.		
		Admitted.	Died.	Constantly sick.
Bengal Native Army	40,753	1076	14·18	34
Madras Native Army	27,043	675	13·96	26
Bombay Native Army	22,701	1243	26·01	43
Central India Regiments	5,112	700	11·54	19
Punjab Frontier Field Force	10,576	1152	14·50	35
Hyderabad Contingent	6,969	522	7·37	17
Total	115,486	978	16·09	32

This shows the sickness and mortality in the Bombay Native Army to have been much higher than in any of the other divisions. The most healthy force was the Hyderabad Contingent. The unfavourable results as regards Bombay were due to the excessive amount of sickness and high death-rate among the portion of the force in Southern Afghanistan, the admissions having been 2832 and the deaths 100·81 per 1000 of the strength of the troops employed there. Malarial fevers, though less prevalent than in any of the five preceding years, were the chief cause of sickness, having given rise to upwards of four-tenths of the admissions. Diseases of the respiratory system caused the highest ratio of deaths, and next to them fevers. Cholera was less prevalent and fatal than in 1884.

The average number of prisoners in the gaols of India was 82,650; the admissions into hospital were 1014 and the deaths 33·54 per 1000—the former being slightly under and the latter 4·43 per 1000 above the proportion in 1884. In Bengal the admissions were 1060, in Madras 705, and in Bombay 645 per 1000; and the death-rate was 38·40, 17·86, and 33·76 per 1000. Bengal shows a very high proportion of sickness and mortality, and Bombay, while having a low rate of admissions, has a high death-rate. The range in the death-rate was very great, being from 2·52 per 1000 in Salem Gaol (Madras Presidency) to 171 in Julpaiguri Gaol (Bengal). The latter very high rate is attributed to overcrowding, defective ventilation, and very bad drainage outside and inside the walls. The results for Madras are very satisfactory, the death-rate being the lowest on record; its steady decrease during the last six years furnishes strong evidence of the value of sanitary measures judiciously applied. Among the gaol population of India generally, intermittent fever was the cause of 371 admissions per 1000, or upwards of one-third of the whole. Dysentery and diarrhœa gave rise to the highest death-rate, being in the proportion of 11·18 per 1000 of strength, or one-third of the total mortality. Diseases of the respiratory system were fatal in the proportion of 5·01, and cholera of 3·44 per 1000. "When compared with the rates for past years, those for 1885, although still high in many cases, show considerable improvement; but enough has been said to show that in many gaols, especially those of Bengal, much improvement is still required, the nature of which can be readily learned from the disease and death statistics and from the gaol sanitary sheets."

The registration of deaths in India is still so imperfect that the results, as shown by the returns, must be greatly under the truth. For instance, as regards Bengal, it is stated that there is no record of the deaths caused by a cyclonic storm which occurred in Orissa on Sept. 22nd, and which are estimated to have amounted to about 15,000.

From the reports of the Sanitary Commissioners it appears that the questions of water supply and of drainage continue to receive attention, and much good work has been done in connexion with both; but the usual difficulty of inadequate funds greatly retards the progress of the improvements. The acting Sanitary Commissioner for Madras points out "the need for a sanitary engineer qualified to give advice to local bodies with regard to water supplies and drainage," and believes that "if such an authority were available, a great impetus would be given to sanitary works." During the year a new Act, called the Madras Local Boards Act of 1884, was passed. Under it a Board has been constituted in each district whose duty it is to provide "for the improvement of village sites and water supply, for sanitary arrangements during fairs and festivals, for the scavenging of small towns and large villages, for the construction and repair of markets, slaughter-houses, latrines, dustbins, and drains, and other measures calculated to promote the health, comfort, or convenience of the people." If the provisions of this Act are efficiently carried out, they ought to be productive of very beneficial results on the health of the general population of the Presidency.

AIR SUPPLY OF THE NAVY.

THE half-yearly course of instruction for naval surgeons on their first entry into the service was commenced on Monday, Sept. 5th, at the Royal Naval Hospital at Haslar. The Director-General of the Medical Department of the Navy, Sir John Watt Reid, K.C.B., was present, and welcomed the newly-appointed surgeons, giving them, as usual, a few words of useful advice and encouragement; after which, Surgeon Gilbert Kirker, M.D., R.N., who is appointed to the hospital to assist Fleet Surgeon Walter Reid, M.D., R.N., in the instruction of surgeons, proceeded to give a historical account of the air supply of the navy. By the air supply is not meant the narrower subject of the renewal of the air or ventilation, but the condition of the air as it surrounds and is breathed by the inhabitants of the ship, or, more briefly, the climate between decks. The history of the subject recognises four periods. The first extended from the earliest times until about the middle of the last century. This was the dark age of hygiene in general, when not only were no attempts made to render more healthy the conditions of life, but when the belief existed that to do so would be a profane interference with the workings of Providence. On board ship, from overcrowding, from the emanations from the putrefying bilge water and foul ballast, from sodden decks and the absence of ventilation, the air supply was inconceivably impure, warm, moist, and stagnant. After a four or eight hours' immersion in this foul vapour bath, the men had to go on deck and bear exposure to the elements. It is worthy of being remembered, too, that when the weather was most inclement on the upper deck the atmosphere was most impure on the lower. Striking to the men themselves must often have been the evil consequences of this sudden change, and it may be suggested that the proverbial dread which sailors have for anything approaching movement in the air of their berths is partly a tradition of their calling, handed down from those ancient evil times, and partly acquired by living yet on lower decks, whose atmospheres, though not grossly foul, are still impure. The second period in the history of the air supply of the navy began about the middle of the last and ended about the second decade of the present century. It embraces a time when the country was struggling in many quarters of the globe for the supremacy of the seas, which meant also national existence. By the contest, the energies of our ancestors were strained and quickened, and they at last perceived that the efficiency of the navy depended on the health of its fleets, and this, again, on the sanitary condition of the ships. This was the time of Lind, Blane, and Trotter, when naval hygiene had its birth. And not only was the practice of preventive medicine inaugurated, but the curative part of naval medical work was put on a better foundation, for then the treatment of sick sailors in hospitals on shore was first properly established, and Haslar and Plymouth Hospitals stand as monuments of this important epoch. The changes leading to improvement in the air supply which took place included the introduction of Lepping's frames in the construction of ships, the use of iron ballast and iron water-tanks, less frequent washing of decks, separation of the sick from the healthy, and better methods of ventilation. The endeavours to improve the air supply must have had some effect. At any rate, the work done in this branch of naval sanitation, combined with that done in others, was followed by a decided improvement in the health of the navy. The statistics are far from complete, but the number of deaths on board ship in 1811 as given by Sir Gilbert Blane was 1 in 30·25, against 1 in 8 in 1779. The length of the existence of individual ships was also increased from seven to thirteen or fourteen years. The third period was one of complete repose as regards endeavours to improve the air supply. When the strenuous exertions of the navy had been crowned with success, a spirit of rest seems to have pervaded the service. Few advances in sanitation were made, and many that had been made were forgotten. Sutton's pipes and Hales's bellows found their way to museums, scuttles were seldom put in ships' sides, and the old windsail became again almost the only special appliance for ventilation. The fourth period, which may be dated from about the middle of the present century, is characterised by great changes in the air supply brought about by the introduction of steam and the rapid development of naval architecture. The introduction of steam, as regards the hygiene of ships, was attended by several serious disadvantages. There was more overcrowding, the continuity of the decks was interrupted, the temperature between decks was raised, and less light was admitted. The health of the seamen suffered, and public attention was forcibly called to the subject by an outbreak of a peculiar pulmonary affection in the Mediterranean fleet. To improve the bad condition of the air supply numerous ventilators were proposed, and the old windsail again saw itself surrounded by young assistants. The numerous cowl-and-tube family arose, the ingenious devices of Inspector-General MacDonald were evolved, and Dr. Edmunds' and Perkins' inventions were brought forward and introduced into several ships. A short time after the revolution in the propulsion of ships, the great revolution in their construction—viz., the employment of iron instead of wood—took place. Looking at the smaller number and diminished size of the lateral parts of iron ships, it was at once concluded that they would prove more unhealthy than their wooden predecessors. This hasty conclusion was not, however, confirmed by inquiry, and, altogether, the use of iron in ship construction has operated in the opposite way, and been attended with a lessening death-rate in the navy. The earlier ironclads of high freeboard have now been succeeded by the modern turret and barbette ships with low freeboard. The sanitary history of these ships has yet to be written, but so far they are not looked on as being more unhealthy than the older ironclads; and with regard to the early American monitors, they were most favourably reported on by the Chief of the Bureau of Medicine and Surgery in 1864. In these low freeboard ships the renewal of the air cannot be effected by the forces naturally acting in the atmosphere, and forces artificially generated have to be resorted to. In the English navy, on board ships of this class, rotary fans draw fresh air from the outside, and drive it along pipes to the places to be ventilated. For the escape of the impure air there is provided a system of pipes leading from the inside to the outside of the ships. Generally, these pipes are merely outlets through which the impure air can exert its ascensional tendency, but occasionally the air is propelled along them by fans. In conclusion, we have seen that the air supply of the navy was once inconceivably bad, that it has improved, but that it is still far from what it should be. The problem of ship ventilation is difficult but not insoluble, and probably the solution will not be approached until naval constructors adopt the system of artificial exhaust instead of artificial supply, and decentralise the application of the force, in order to render unnecessary long branching and bending pipes.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5752 births and 3502 deaths were registered during the week ending October 22nd. The annual rate of mortality in these towns, which had been 17·5 and 17·8 per 1000 in the preceding two weeks, further rose last week to 19·8. During the past three weeks of the current quarter the death-rate in these towns averaged 18·4 per 1000, and was 1·8 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 15·7 in Norwich, 15·8 in Halifax, and 17·2 in Nottingham and in Salford. The rates in the other towns ranged upwards to 23·2 in Huddersfield, 23·2 in Bolton, 25·4 in Sunderland, and 26·4 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined from 461 to 382 in the preceding three weeks, rose last week to 392; they included 117 from scarlet fever, 62 from whooping-cough, 59 from measles, 56 from diarrhœa, 52 from "fever" (principally enteric), 38 from diphtheria, and 8 from small-pox. These zymotic diseases caused the lowest death-rates last week in Plymouth, Nottingham, and Halifax; and the highest rates in Oldham, Blackburn, and Birkenhead. The greatest mortality from scarlet fever occurred in Oldham, Huddersfield, Liverpool, Blackburn, and Birkenhead; from whooping-cough in Newcastle-on-Tyne, and Leicester; from measles in Cardiff, Blackburn, and Derby; and from "fever" in Oldham, Sunderland and Preston. The 38

Digitized by Google

deaths from diphtheria in the twenty-eight towns included 21 in London, 5 in Manchester, and 3 in Brighton. Small-pox caused 7 deaths in Sheffield and 1 in Bristol, but not one in Greater London or in any of the twenty-five other large towns. Only 7 cases of small-pox were under treatment in the metropolitan hospitals receiving cases of this disease; while the number of cases of scarlet fever in the Metropolitan Asylums Board hospitals and in the London Fever Hospital had increased to 2167. The deaths referred to diseases of the respiratory organs in London, which had been 206 and 280 in the preceding two weeks, further increased last week to 370, and were 30 above the corrected average. The causes of 68, or 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Sunderland, and in six other smaller towns. The largest proportions of uncertified deaths were recorded in Liverpool, Sheffield, Bolton, Brighton, Sunderland, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased from 17·7 to 19·3 per 1000 in the preceding three weeks, declined to 19·1 in the week ending October 22nd; this rate was 0·7 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 13·3 in Aberdeen, and 17·8 in Dundee and in Greenock, to 25·6 in Paisley and 34·0 in Perth. The 478 deaths in the eight towns last week showed a slight decline from the number in the preceding week, and included 22 which were referred to scarlet fever, 16 to whooping-cough, 10 to diarrhœa, 7 to diphtheria, 6 to "fever" (typhus, enteric, or simple), 5 to measles, and 2 to small-pox; in all, 68 deaths resulted from these principal zymotic diseases, against 64 and 79 in the preceding two weeks. These 68 deaths were equal to an annual rate of 2·7 per 1000, which exceeded by 0·5 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of scarlet fever, which had increased from 11 to 23 in the preceding four weeks, were 22 last week, of which 10 occurred in Dundee, 7 in Glasgow, 3 in Perth, and 2 in Edinburgh. The deaths referred to whooping-cough, which had been 17 and 30 in the previous two weeks, declined last week to 16, and included 4 in Glasgow and 4 in Greenock. The 10 fatal cases of diarrhœa showed a further decline from recent weekly numbers, and included 4 in Dundee and 3 in Edinburgh. The 7 deaths from diphtheria corresponded with those returned in each of the preceding two weeks; 3 occurred in Glasgow and 2 in Edinburgh. The 6 fatal cases of "fever," of which 3 were recorded in Glasgow and 2 in Edinburgh, differed but slightly from those returned in recent weeks. Of the 5 deaths from measles, 3 occurred in Perth, where also the 2 fatal cases of small-pox were recorded. The deaths attributed to acute diseases of the respiratory organs in the eight towns, which had been 87 and 98 in the preceding two weeks, further rose last week to 120, and exceeded by 32 the number returned in the corresponding week of last year. The causes of 70, or nearly 15 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 24·2 and 27·3 per 1000 in the preceding two weeks, declined again to 24·1 in the week ending October 22nd. During the first three weeks of the current quarter the death-rate in the city averaged 25·2 per 1000, the mean rate during the same period being but 17·3 in London and 18·4 in Edinburgh. The 163 deaths in Dublin last week showed a decline of 22 from the number in the previous week; they included 8 which were referred to scarlet fever, 6 to diarrhœa, 6 to "fever" (typhus, enteric, or simple), 5 to measles, 4 to whooping-cough, and not one either to small-pox or diphtheria. Thus the deaths resulting from these principal zymotic diseases, which had been 29 and 36 in the preceding two weeks, declined last week to 29; they were equal to an annual rate of 4·3 per 1000, the rate from the same diseases being but 2·0 in London and 2·2 in Edinburgh. The deaths referred to scarlet fever, which had increased from 1 to 11 in the preceding three weeks, declined to 8 last week. The 6 fatal cases of diarrhœa showed a further decline from recent weekly numbers; and the 6 deaths referred to "fever" were within one of the number in the previous week. The fatal cases of whooping-cough showed an increase, while those of measles were fewer than in any recent week. The deaths both of infants and of elderly persons showed a decline from the numbers in the preceding week. Eleven inquest cases and 6 deaths from violence were registered; and 36, or nearly one-fourth, of the deaths occurred in public institutions. The causes of 21, or more than 13 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Deputy Surgeon-General W. Marshall Webb has joined at York from Edinburgh, and taken over the duties of Principal Medical Officer of the Northern District; Surgeon-General Irvine has rejoined at Madras from leave on medical certificate, and has assumed the duties of Principal Medical Officer of the British Troops in the Madras Presidency.

The Greenwich Hospital pension of £50 a year for medical officers, vacant by the death of Deputy Inspector-General J. W. Elliott, M.D., has been awarded to Staff Surgeon John Stewart, M.D.

WAR OFFICE. — Medical Staff: The undermentioned Surgeons-Major are granted retired pay, with the honorary rank of Brigade Surgeon (dated Oct. 26th, 1887):—John Langdon and Henry Jagoe, M.B.

The Queen has approved of the following promotions made by the Government in India:—Surgeon-Major Robert Gray (dated 3rd June, 1887) and Surgeon-Major Joseph Macnaughton Fleming, M.D. (dated Aug. 6th, 1887), of the Bengal Medical Establishment, to be Brigade Surgeons.

ADMIRALTY. — The following appointment has been made:—Surgeon William S. Lightfoot, to the *Téméraire*.

ROYAL NAVAL ARTILLERY VOLUNTEERS (London Brigade).—Cecil Rupert Chaworth Lyster, to be Surgeon (dated Oct. 24th 1887).

ARTILLERY VOLUNTEERS.—1st Fifeshire: John Wilson Moir, M.D., to be Surgeon (dated Oct. 22nd, 1887).

Correspondence.

"Audi alteram partem."

"THE PRESYSTOLIC MURMUR, FALSELY SO CALLED."

To the Editors of THE LANCET.

SIRS,—With your permission, I will first refer to some facts which appear to be inconsistent with the theory that the so-called presystolic murmur is the result of mitral regurgitation, and I will then reply to some objections which have been made to Dr. Gairdner's auriculo-systolic theory.

All observers will, I think, agree that, however intense may be the murmur in question, the sound is heard only at the heart's apex, or in the immediate neighbourhood thereof, and that it is rarely, if ever, audible at the back of the chest. In this respect there is a marked contrast between the murmur of mitral constriction and the acknowledged mitral regurgitant murmur, which, although usually less intense over the heart's apex than the presystolic murmur, is, in the great majority of cases, distinctly audible at the back, near the angle of the scapula, and in the left vertebral groove. This difference is explained by the theory that the presystolic murmur is conveyed forwards to the apex of the heart and the anterior wall of the chest by the onward current of blood from the auricle, while the regurgitant murmur is carried backwards by the reflux of blood from the ventricle. It remains for those who maintain that both these murmurs are regurgitant to explain the unquestionable fact that they travel, by liquid convection, in opposite directions.

I have satisfied myself by numerous careful observations that the murmur of mitral constriction and the thrill which accompanies it precede the impulse of the contracting

Digitized by Google

ventricle, and therefore are presystolic in rhythm. With the hand firmly placed on the heart's apex the sharp impulse can be felt to follow and not to accompany the thrill. Again, with a solid stethoscope the harsh murmur can be heard before the short sound and impulse of the ventricular contraction in which it terminates; and thus there is a manifest contrast with the synchronous heaving impulse and the prolonged systolic murmur of mitral regurgitation. In the few cases in which I have noted that a presystolic has been followed by a systolic murmur, there has been a distinct though brief interval between them, coincident with the reversal of the blood stream.

In one carefully observed case of mitral stenosis a soft murmur, commencing immediately after the second sound—therefore diastolic—was continuous with an auriculo-systolic intensification, with the usual accompanying thrill, and this was followed by the short first sound and impulse. In this case the soft murmur attending the passive flow of blood into the dilating ventricle was intensified by the increased impetus imparted to the current by the auricular systole. It is probable that in a large proportion of cases with a constricted mitral orifice, there is imperfect closure of the valve during the ventricular systole and a consequent reflux of blood; and the comparative rarity of a double murmur is probably due to the fact that the ventricular contraction is too sharp and brief to admit of the development of a murmur. On the other hand, it is in the highest degree improbable that when the curtains of the mitral valve have been converted into a rigid funnel, a reflux of blood, supposed to occur at the commencement of the systole, should be abruptly arrested by the close apposition of the segments at a later period. We know from abundant experience how slight a thickening and unevenness of the margin of the mitral curtains suffice to render the valve incompetent—an incompetence which the continuous systolic murmur shows to persist during the whole period of the ventricular contraction. What evidence have we that an undoubted mitral regurgitation is ever abruptly arrested towards the close of the ventricular systole, and that a mitral systolic murmur terminates in a sharp first sound and impulse?

It has been objected to the auriculo-systolic theory of the murmur that in the absence of valves to prevent reflux, the auricular contraction would be insufficient to cause a murmur in a constricted mitral orifice. Now, in reply to this, it is notorious, as has been well remarked by Dr. Shearar at the close of his letter in your last issue, from the easy production of the *bruit de diable* in the veins of the neck, that for the causation of a loud murmur very little force or rapidity of the blood current is required. Then there is evidence that the force of the auricular contraction, passing in a vermicular manner from the veins towards the auriculo-ventricular opening, is by no means small, as was demonstrated more than two centuries and a half ago by our immortal Harvey. He says:[1] "After the heart has ceased to beat, the auricles, however, still contracting, a finger placed upon the ventricles perceives the several pulsations of the auricles precisely in the same way and for the same reason, as we have said, that the pulses of the ventricles are felt in the arteries—to wit, the distension produced by the jet of blood; and if at this time, the auricles alone pulsating, the point of the heart be cut off with a pair of scissors, you will perceive the blood flowing out upon each contraction of the auricles." It should also be borne in mind that, as a result of mitral stenosis, the contractile and propulsive force of the auricle is much increased by hypertrophy of its walls.

It has been objected to the auriculo-systolic theory that it is improbable that a murmur more intense than that associated with most cases of unquestionable mitral regurgitation should be caused by the contraction of a cavity whose walls are so much less powerful than those of the ventricle. To this objection the reply is that the intensity of a murmur depends not solely on the force of the blood stream, but mainly upon the condition of the orifice through which the current is propelled. In illustration of this I need only refer to the fact that in cases of double aortic murmur the diastolic is usually louder and often much more intense than the systolic; yet it is certain that the regurgitant current of blood must be less forcible than the direct onward stream. The difference between the two sounds is explained by the fact that the defective sigmoid valves are in a position to vibrate more readily and audibly under the influence of the regurgitating than of the direct blood stream.

The probable explanation of the comparative loudness of the direct mitral murmur is that during the diastole of the ventricle, the columnæ carneæ being relaxed the thickened curtains of the mitral valve therefore not being dragged upon by the cordæ tendineæ, are thrown, like a flag flapping in the wind, into very audible and palpable vibrations. On the other hand, during the ventricular systole the margins of the mitral segments are so restrained by the contracting fleshy columns and the tense tendinous cords, that the sound resulting from a forcible reflux current is usually less intense than the murmur of mitral constriction.

Dr. Dickinson has satisfied himself, by means of a pin in a piece of cork placed over the heart's apex, that "the so-called presystolic murmur does not precede the impulse of the heart, but begins with it; in strictness it is systolic, not presystolic."[2] He confesses the difficulty of making "two senses work together in exact consent"; but even admitting that Dr. Dickinson's observations are correct, and that the murmur of mitral constriction and the movement of the pin were synchronous, if cardiographic observations are to be relied upon, it is probable that the first vibrations of the pin were caused, not by the ventricular but by the auricular systole. I have no practical experience of the cardiograph, but I learn from the tracings and the description given by Landois,[3] that the first impulse communicated to the button and the first rise in the cardiographic tracing are attributed to the contraction of the auricles. If this be so, it appears not unlikely that Dr. Dickinson's observations, correctly interpreted, contravene his own theory.

In a paper which was published in THE LANCET some years since (May 13th, 1876) I have endeavoured to prove that the auricular systole is directly concerned in the production of three distinct sounds: (1) The presystolic friction sound of pericarditis; (2) the auriculo-systolic murmur of mitral constriction, as first clearly described by Dr. Gairdner; and (3) the first division of the double first sound in cases of obstruction of the systemic or pulmonic circulation.

I am, Sirs, yours truly,

Savile-row, W., Oct. 24th, 1887. GEORGE JOHNSON.

[1] De Motu Cordis et Sanguinis. College edition, p. 29. Dr. Willis's translation, p. 27.

[2] THE LANCET, p. 681.

[3] Text-book of Human Physiology, translated by Stirling. Second edition, vol. i., p. 89.

To the Editors of THE LANCET.

SIRS,—Professor Gairdner has made so admirable a defence of the all but universally recognised rhythm of the auricular-systolic murmur, that it seems quite superfluous for me to make any addition to his lucid statements. And yet, with your permission, I should like to make a few remarks upon some of Dr. Dickinson's statements which seem to require a little explanation.

The great inducement to adopt the ventricular-systolic or regurgitant theory of the auricular-systolic murmur appears to be the difficulty experienced in acknowledging so apparently feeble an organ as the auricle to be the source of so loud and rough a murmur. To my mind, it seems even more remarkable that the ventricle should be supposed capable of producing this loud rough murmur at the first beginning of its systole, when it is acknowledged that as this systole nears its acme and gains in force, the murmur grows less rough, and finally becomes soft and blowing. Dr. Dickinson seems to consider that because the pulmonary vessels are elastic the analogy to a Bramah press fails. But I merely referred to the Bramah press as a well-known illustration of the law that fluid within a confined area presses equally in all directions, and I am not aware that the greater or less elasticity of the containing walls has any power to modify this law. Unquestionably the pulmonary bloodvessels undergo many serious changes through the influence of the increased blood pressure within them, which would not happen if they were made of cast iron; but I do not see that my argument is in any way weakened by this. In relation to this matter, it is also interesting to remember that so long as the intra-pulmonary blood pressure remains high, and the auricle is thus stimulated to extra exertion, just so long does the auriculo-systolic murmur remain loud and rough. But whenever the

Digitized by Google

intra-pulmonary blood pressure gets lessened under the influence of tricuspid regurgitation, then the force of the auricular-systolic murmur begins to fail, and in no long time it ceases altogether, the soft ventricular systolic murmur alone remaining.

Again, Dr. Dickinson says that possibly "the auricular contraction may be assisted in moving the blood by the expansile or suction action of the ventricle" (p. 651); and in another place he argues that the murmur of "mitral obstruction must succeed the second sound with an interval," because after the conclusion of its systole there "is a period during which the ventricle waits empty and still, and not until it reopens can the blood enter from the auricle" (p. 695). Now, *Hope* says that the expansion of the ventricle immediately succeeds its active contraction (3rd ed., p. 19), and I know of no modern observations tending in the least degree to invalidate this statement. It follows from this that, if there be a diastolic mitral murmur, it must accompany the second sound and follow it without an interval, running on till the diastolic ceases and the period of rest succeeds. The duration of the diastolic mitral murmur is thus a measure of the amount of stenosis present, and this I have always found to be the case. Neither can the onward movement of the blood by the auricular systolic be aided by the ventricular diastolic expansion, because the latter precedes the former.

Further, Dr. Dickinson objects to the term *continuous* being applied to the double murmur audible at the apex in many cases of mitral stenosis, and composed of the rough auricular systolic murmur, immediately followed by the blowing ventricular-systolic murmur. To this I have no objection; the one murmur runs up to the other; but *continuous* is perhaps scarcely the word to apply to them. The auricular-systolic murmur runs up to, and is continuous with, the ventricular systolic (regurgitant) murmur, in the same sense of the word that the aortic-systolic murmur may be said to run up to, and be continuous with, the aortic-diastolic (regurgitant) murmur, and when the systolic portion of this latter murmur is rough the analogy is very complete. In neither case is there any appreciable interval between the two portions of the murmur, except in certain very rare cases, which may happen to both classes of murmurs. Dr. Dickinson says, "Thus two murmurs, belonging, according to this belief, to different parts of the same act, may be separated by an appreciable interval; while two murmurs, the presystolic and the systolic, belonging to different acts, and made by the blood going opposite ways, may be inseparably blended together. This does not present itself with an air of probability." It will be seen from the foregoing that his quarrel is with physiology and with facts, and not merely with opinions.

I am, Sirs, yours obediently,

Edinburgh, Oct. 25th, 1887. GEORGE W. BALFOUR.

To the Editors of THE LANCET.

SIRS,—May I beg space for a few considerations which I think have an important bearing on the mode of origin of the presystolic murmur, so called?

It has been assumed that the loudness and roughness of the murmur characteristic of mitral stenosis indicate great intensity of vibration, and on this assumption it has been argued that so feeble a structure as the left auricle could not contract with the requisite amount of vigour. I will pass over the fact of auricular hypertrophy, which in many cases of mitral stenosis is so striking (though this of course bears directly on the question of auricular inadequacy), and will simply ask the question, Are the vibrations of the bruit of mitral stenosis actually so intense? Now, in the first place, the roughness of a sound tells us of the amplitude of the component vibrations, not of their intensity; and, in the next place, the loudness of a sound, though *cæteris paribus* a measure of intensity, is not so when "the other things are not equal," and hence is not a measure of intensity applicable to murmurs of different pitch, and (probably) of different mode of origin. A very simple experiment will explain. Let the teeth be shut and the lips simply in contact in their natural position or very gently pressed together; it will then be found that the breath rather sharply puffed out, though without much force, will throw lips and cheeks into loud-sounding vibration. Let the lips now be screwed up into the position for blowing, and the breath driven out with all the energy at our command; the sound produced will be quite different in quality, and in loudness will not compare with the first sound produced. Is loudness in this case a measure of the force expelling the air in the two cases? Perhaps it may be well to observe that on the commonly accepted view of the auricular systolic origin of the presystolic bruit, the conditions under which this bruit arises are not so unlike those under which the lips and cheeks are thrown into loud and coarse vibrations, for in either case a puff of fluid is suddenly projected through an opening surrounded by *relaxed* structures; and, again, that the forcible expiration through the screwed-up lips resembles in its results the blowing murmur of ordinary mitral regurgitation; also that in each case we have a stream of fluid under high pressure issuing from an aperture surrounded by parts *on the stretch*.

I will not dwell further on this point, but will pass to the next consideration. A very constant attendant upon the bruit of mitral stenosis is the thrill. So constant is it that one is compelled to ask the question why this bruit more than others should be so attended? The reasons are, I think, not far to seek on the auricular systolic theory. On this theory we have the left ventricle becoming gradually distended under *low pressure* from the moment of ending of the ventricular systole. Just before the auricular systole begins, we have close under the hand over the area of the apex beat a bag of fluid, its walls but very moderately on the stretch, and themselves in a state of relaxation and at their thinnest. Into this somewhat flaccid bag the sudden contraction of the auricle sends a puff of fluid across the unstretched lips of the mitral valve: conditions more favourable to the production of a coarse, tremulous movement, and to the propagation of the same to the chest wall, I can hardly conceive of; and that a sound like the rumble of mitral stenosis, obviously near the lower limit of the scale of audible sounds, should be so readily appreciated by the hand is at once evident.

In conclusion, let me only contrast with this the receding and hardening and thickening ventricular walls during systole. It will then, I think, become apparent why a bruit of regurgitation, even though other things were equal, should be less frequently attended by a thrill. Different but adequate reasons might, I think, be assigned for the relative infrequency of a thrill in an aortic regurgitation as compared with mitral stenosis.

I am, Sirs, your obedient servant,

Welbeck-street, W., Oct. 18th, 1887. HARRINGTON SAINSBURY.

THE HONOURS EXAMINATIONS OF THE UNIVERSITY OF LONDON.

To the Editors of THE LANCET.

SIRS,—Dr. Vincent Harris has done good service in drawing attention to the injustice inflicted on candidates for the Preliminary Scientific and Intermediate M.B. Examinations by the new regulations, which require a candidate to select and compete for an Honours Examination before having secured a Pass. This is a retrograde step promulgated entirely in the interests of the executive, without reference to the uses of the examination. It is a red-tape movement to save time and labour on the part of those who arrange the examinations and those who deliver judgment on the competitors; whilst the effect on the candidates is to cause the most worthy to withdraw from competition, and thus leave the examination an altogether unjust test of superiority. Those who have a large experience in teaching know how difficult it often is to induce the most industrious and intelligent students to compete for honours, because a natural modesty so frequently accompanies true merit. Moreover, those who work hardest often dare not risk (from financial considerations) the chance of rejection. They cannot therefore be even advised to enter for the present Honours Examination; but had they (as under the old regulations) relieved themselves of the anxiety of a pass, they then could with good heart be induced to compete for honours. Is it to be supposed that among the six candidates from Guy's Hospital who took a first division at the Pass there were not those who, as in former years, would have attained to some of the highest positions in honours? The reputations of these men should lie heavily on the heads of those who framed the new regulations, for whatever may have been our misfortunes at Guy's Hospital, the hard work and energies of our students could never have been in question.

Digitized by Google

The experimental legislators of the University may have irretrievably damaged the future of some of these candidates, and have set up an inferior standard of merit by excluding some of the most brilliant competitors. Are there not some young men on the Senate who will protest against these signs of senility in our University? If the examiners are overworked, let more be appointed; do not limit competition by framing regulations to hamper those most competent to compete.

I am, Sirs, your obedient servant,

R. CLEMENT LUCAS, B.S., M.B. Lond., F.R.C.S.

Finsbury-square, Oct. 24th, 1887.

To the Editors of THE LANCET.

SIRS,—May I be allowed to add my testimony to that of Dr. Vincent D. Harris in your last issue? As far as I am able to ascertain, the new rule relating to the Honours Examination at the Intermediate Bachelor of Medicine Examination of the University of London is unpopular both amongst teachers and students. For reasons which Dr. Harris mentions the teacher is often reluctant to advise students to compete for Honours. The efforts of the student are, in consequence, less strenuous and his attainments smaller. Should the University authorities undertake this question, a collateral one might also be considered. I believe that at present a candidate may, after failing to pass at one examination, present himself for honours at the next, and perhaps carry off the highest. There are some who think this anomalous.

I remain, Sirs, sincerely yours,

C. B. LOCKWOOD.

19, Upper Berkeley-street, Portman-square, W., Oct. 27th, 1887.

To the Editors of THE LANCET.

SIRS,—Dr. Vincent Harris's letter in your issue of Oct. 22nd shows that of all the medical schools Guy's passed the most men in the first division, and yet had none in the honours list. It was as Dr. Harris suggests—namely, that all these six men preferred trying for a good pass to competing for honours under the present conditions, which the majority of those interested in the matter would like to see abolished.

I am, Sirs, yours truly,

Harley-street, W., Oct. 25th, 1887. W. HALE WHITE, M.D.

THE NEGLECT OF BLOODLETTING.

To the Editors of THE LANCET.

SIRS,—The history of the illness of Sir William Gull, as stated in your last number, may well give occasion to inquire whether the neglect or abandonment of bloodletting is altogether wise. Thus, quoting your account: "The one feature in the case which has been the occasion of special anxiety has been a certain hæmorrhagic tendency. Last year he had hæmoptysis, and, later, profuse epistaxis. At the time of this occurrence he had slight and transient, but marked hæmaturia, and in the light of this the brain lesion cannot escape being ascribed to a similar cause." The rational deduction from this sequence of events is clear. The three or four distinct outbreaks of extravasation of blood at different points of the circulation demonstrate hyperæmia, relative or absolute, and vascular tension. The obvious therapeutical indication is to lower the tension, to reduce the volume of blood. To accomplish this, and thus to anticipate nature seeking relief by dangerous outbursts, the obvious remedy is to let blood. This may be done in one of two ways—(1) by a small derivative bleeding from the arm; (2) by cupping. But venesection and cupping are nearly lost arts; and certain it is that valuable lives are lost in consequence. Bleeding has fallen into such oblivion, not to say under such condemnation, that I suppose it would require, not simply a consultation, but the consensus of a College or a Congress to sanction resort to it. We now have in the sphygmograph a trustworthy aid in the determination of the conditions that indicate the expediency of bloodletting. But this admirable diagnostic instrument is shorn of half its value if its practical teaching is neglected.

I am, Sirs, yours &c.,

[illegible], October, 1887. ROBERT BARNES.

THE GENERAL MEETING AT THE COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—Will you allow us to remind your readers of the approaching general meeting at the College, to be held on Thursday, Nov. 3rd, at 3 P.M. Considering that at the present moment the petition from the Council of the College for a supplemental Charter, and that of the Members of the College for various much-needed reforms unnoticed by the petition of the present rulers of the College, lie side by side, or rather face to face, before the Privy Council, it is of even greater urgency than on previous occasions that the meeting be fully attended. We must remember that it is now no longer a question of internal policy, and one to be arranged by accommodation within the College walls, but one of an appeal to the authorities outside. The Members must show that their interest in this matter is paramount. We have, however, no fear upon this head, for the signatures, amounting to nearly 5000, to the Members' petition warrant us in the conviction that we have the bulk of the profession with us. A brief reference is made in the Council's annual report to its late offer to meet a small number of representatives of the two Associations of Fellows and of Members; but as that offer was rendered nugatory by the proviso that the Council was not prepared to give any effect to the first resolution passed at the last general meeting, the offer was very properly declined, its wording excluding any hope of concession. Other matters are also referred to, such as the refusal of the Council to alter its decision as to the vital matter of co-operation with the Society of Apothecaries, even though the expressed wish of the Members was emphasised by the Medical Council itself; the result is that two complete diplomas are now granted in the metropolis by competing bodies. But as these points will be fully dealt with on Nov. 3rd, we need only now repeat our request that the Members muster on that day in full force.

We are, Sirs, your obedient servants,

WARWICK C. STEELE,
WM. ASHTON ELLIS,
Hon. Secs. Assoc. of Members of the
Oct. 25th, 1887. Roy. Coll. of Surg.

NOTIFICATION OF INFECTIOUS DISEASE.

To the Editors of THE LANCET.

SIRS,—The subject of compulsory notification of infectious disease having recently occupied considerable attention in the columns both of the medical and public press, perhaps the experience of one who speaks from an actual extended acquaintance with the same may be of some use in arriving at a conclusion upon this subject. And here it should be noted that this is a question in which the public at large are even more interested than the medical profession itself.

If any health authority is to grapple successfully with outbreaks of epidemic disease, the first and most elementary requisite is that they should at once, and with the smallest delay possible, know where such disease exists. Upon this surely all are agreed. Then comes the question respecting which so much difference of opinion exists—i.e., the best way of supplying this information to the authority concerned. Shall it be through the medical attendant, or through the friends of the patient, or both? Practically it must in the great majority of cases come from the medical attendant directly or indirectly. This being so, why complicate matters by introducing a third person, often ignorant, illiterate, or harassed, and only tending to cause delay in the information being received? Surely the medical man is the fittest person, and there is nothing more *infra dig.* in thus reporting than in furnishing the legal certificate of death in fatal cases. But to meet the smaller minority of cases where no medical attendant is called in, the notification should be dual, the responsibility resting equally on the patient's friends as on the practitioner, and then the objection is efficiently met that cases would be wilfully concealed by patients not having any medical attendant at all. Leicester was among the first of the large English towns to obtain these compulsory powers, and the strongest opposition was raised at the time by the members of the profession here. It was asserted that the confidential

Digitized by Google

relations existing between doctor and patient would be destroyed, &c. Nine years' experience has served to dispel all these fears, and to-day those who were then amongst the most determined opponents are now its warmest supporters. The dual system is in force, but in practice only the medical man certifies, though the public are kept fully alive to the fact that they also may be called on to notify, and thus the hiding away of cases is prevented. No doubt, where a medical officer of health is also in general practice, there will exist a not unreasonable dislike to notify to a rival practitioner; but in all our large towns, where that official is not engaged in practice, he must be wanting considerably in tact and discretion if any friction arise between him and his professional brethren on this matter.

I am, Sirs, yours faithfully,

HY. TOMKINS, M.D., B.Sc., San. Sci. Dipl.,
Leicester, Oct. 25th, 1887. Medical Officer of Health.

THE DUAL NOTIFICATION CLAUSE.

To the Editors of THE LANCET.

SIRS,—The dual notification of infectious diseases has an important bearing in two directions: first and foremost as to the best way of preventing the spread of infectious disease; and, second, as to the rights of medical men in private practice. The question was raised at the recent Sanitary Congress in Bolton, and a great amount of special pleading and one-sided opinion was expressed by some of the large body of medical officers of health who were assembled at that important Congress. I fear I was considered a *bête noire* for opposing the principle of dual notification. Having been one of the earliest of living sanitarians who advocated the appointment of medical officers of health in every place, long before the majority of those now appointed had any knowledge of sanitary work, and also having brought to the notice of the public through the Social Science Association the absolute necessity for immediate notification to the State official of the presence of infective disease in our midst, are points which should satisfy your readers of my desire to obtain such notification, and also of my belief in the benefits to be obtained from it. Nevertheless I am sorry to see my official brethren trying to obtain that notification by a means which will assuredly fail in its purpose. The truth of my assertion was fully borne out by the experience afforded at the Bolton Congress. Several of the readers and speakers in favour of dual notification, including Mr. North of York, stated that they had never had a notification forwarded to them by the householder, and in Bolton itself it was the exception. In the latter town there is considerable friction between the medical officer of health and his professional brethren upon this subject. In many towns the complaint is made that a large percentage of the cases of death which were registered were uncertified by medical men. In some instances this amounted to 10 per cent. of the actual number of deaths, and Mr. Vacher was very pertinent upon this point in his valuable paper. Yet the medical officers of health are insisting upon dual notification, whilst they allow the law when obtained to be a dead letter as far as one section of the parties to dual notification are concerned. At Bolton the chairman of the Sanitary Committee, evidently animated with a feeling of hostility towards defaulting medical men, makes no effort to put the law in force against the householder, who in that place ignores the law altogether. What is the result? A very large percentage of infectious cases have no medical attendant, and disease spreads in consequence. The action of the medical officers of health all over the kingdom shows that they do not believe in dual notification, and I am in accord with them as to one notification being sufficient. A dual notification is absolutely unnecessary, and those districts in which the local authority pays for the certificate when forwarded by the medical man get the certificate from the medical attendant whether there is a penal clause or not. My view of the matter is this. Let the medical attendant have a right to claim a fee of not less than 2*s.* 6*d.* for the certificate from the local authority. Let the medical attendant have the right to be the agent of the householder in communicating with the medical officer of health, and make it penal upon the householder or guardian if he does not make the communication either by himself or his agent. There will then be an end of all friction between the medical officer of health and the medical attendant. The former will not be able to say of his medical *confrère* that, if he does not send in the certificate, he will put him in the dock at the police-court. As the law at present stands, if the householder fails, and the medical attendant also does not send a certificate, the latter is a *particeps criminis*, and the medical officer of health cannot call him as a witness against the defaulting householder or guardian. If there is no penal clause against the medical man, the medical officer of health can put the practitioner into the witness box, and ask if he did communicate to the proper persons the fact that the case which is the subject of the charge was infectious and should be isolated. If the doctor says "Yes," the case may be established against the defendant; if he says "No, I did not," the medical man publicly acknowledges that he failed in his duty to his patient, and the local press would know how to deal with him. I believe that a few cases of such a character would put an end to all attempts on the part of private persons to conceal disease, and there would be no object in not having medical attendance. It is quite certain that medical men as a class could not be parties to such a desire. If a private practitioner is so little careful of his duty towards his patients and their friends as not to inform them of the danger of infection, he is liable to action by the defendant himself, and public opinion would soon put an end to his private practice. Whilst, if he connived with his patient's friends, an acute lawyer would soon show by cross examination that he was rendering himself liable to prosecution for perjury. It is very important, in the interests of the State and of sanitary progress, that the notification should be real, not nominal. It is a bad principle, though occasionally necessary, to allow a penal clause to be a dead letter, but to assist in obtaining such a clause for the purpose of allowing it to be in abeyance is ridiculous. This is accepted by the medical officer of health as against the householder, and I know it is not put in force against medical men in some districts of the country. Dual notification, as at present carried out, is a farce, for it is not dual. Experience shows that one certificate is sufficient for the purposes of registration—that, indeed, it is better than two. The medical attendant will always act as the agent of the patient if the law allows the payment for the certificate; and it is altogether contrary to justice for a professional rival to have the opportunity of saying of his brother practitioner that, if he does not send in his certificates quickly enough, he will put him in the dock at the police-court. The State has no right to make medical men State officials until the position of the medical man is recognised by the State in a very different manner to that which is accorded to the profession at the present time; and if I were in general practice I should decline to send in any certificate without first obtaining the consent of my employer to that course. As the law is now carried out, dual notification is a farce, and open encouragement is given to large numbers of people to avail themselves of unskilled medical attendance, or to do without it altogether. This is seriously adding to the difficulty of repressing disease. A single notifying clause as against the householder, with another giving the right to a fee for the notifying doctor, would be far more effectual than the dual plan, which is only teaching people how not to do it, and making them disobey the law.

I am, Sirs, your obedient servant,

Croydon, Oct. 14th, 1887. ALFRED CARPENTER.

HEMIPLEGIA DURING THE PUERPERIUM.

To the Editors of THE LANCET.

SIRS,—I beg to respond to Dr. Sloan's request in your issue of the 8th inst. that readers of the paper would record their experience of hemiplegia during the puerperium *sine* valve disease. Ten years ago (in the September number of the *Edinburgh Medical Journal*, vol. xxii., p. 922) I recorded a case of "Puerperal Embolism; Aphasia; Hemiplegia; Recovery." I would refer Dr. Sloan for fuller details to the brief account in the journal quoted; but a synopsis of the case is: "Parturition on April 15th, 1877; good puerperium. Mental worry on May 2nd; sudden loss of speech; faintness; cramp-like pain referred to calf of left leg. The condition of the heart and kidneys normal; no history of rheumatism. (These facts, referring to *heart* and kidney, on May 2nd, from my note-book, do not appear in the published case.) On May 4th patient spoke monosyllabically. May 5th: Kidneys normal; no symptom of metria or septicæmia; right arm paralysed. May 23rd: Speaking better, but not perfectly; sensation of right arm and leg almost normal;

Digitized by Google

muscular coördination and power very much restored to arm; leg still almost motionless." My summary of the diagnosis reads: "The continued, prolonged nature of the case" (there was subnormal power in the limbs in the middle of July), "the evident absence of mental disturbance of the higher centres—e.g., those of rational thought,—the implication of the tongue and eye, the gradual development of hemiplegia, the want of the peculiar 'heel dragging' in walking, and the slow, lengthened convalescence, negative such a supposition"—viz., a suggestion previously made of hysterical paralysis; and—"We have here a history of interrupted brain function of the special centre of speech followed by hemiplegia of the right side ..... the left middle cerebral artery had been suddenly occluded, and the consequent train of symptoms indicative of impaired arrested function of the left frontal convolution, of the left corpus striatum, and convolutions in its vicinity, followed."

As illustrating what I esteem a still rarer condition in the puerperal, I would refer your readers to a case of left-sided hemiplegia associated with albuminuria and kidney affection. I believed the paralysis to be of reflex nature; the account is published in vol. ix., p. 122, of the Transactions of the Edinburgh Obstetrical Society. In this case paresis with aphasia and drowsiness came on, on April 26th, 1880. Amaurosis had been noted on April 22nd. A reference to the volume named will show a wholly dissimilar clinical history to the one quoted formerly. "Delivery on May 5th of living but weakly child; no eclampsia; return of muscular power to hand longest delayed. By middle of June patient recovered."

In connexion with the subsequent discussion, to which the late Dr. Angus Macdonald made a most invaluable contribution, he incidentally suggested (p. 192, vol. ix., Trans. Obstet. Soc.) the possibility of embolus or "sand grain" apoplexies as explanatory of the pathology. My friend Dr. Underhill was also inclined to accredit miliary aneurysms or embolism as a likely pathological explanation. My reply on the discussion touched on the further grounds which seemed to me to warrant a diagnosis of "reflex paralysis." The history of two other cases of puerperal aphasia in abstract, with an interesting post-mortem account extracted from the *Allgemeine Medicin Central-Zeitung* (No. 33, 1879), will be found in the *British Medical Journal*, vol. ii. 1879, p. 882. In my paper previously mentioned, I remark: "Both seem to have been due to inflammation. ..... Dr. Lewandowski's case suggests encephalitis, and the other was plainly inflammatory and pyæmic. On post mortem the left anterior convolutions contained a decomposed focus the size of a nut; purulent foci were found in the lungs and uterus, with suppuration of the veins of the ovario-uterine plexus, &c."

Although puerperal aphasia, apart from septic influences, is not common, I believe several cases of simple embolic aphasia during the puerperium are to be found on record. I can conceive no general condition of the blood more likely to predispose thrombosis and embolism than that found in pregnancy. At the same time, temporary absence or late appearance of murmurs cannot always be left out of count in valve lesions, as shown in Dr. Dickinson's very interesting paper on the "so-called Presystolic Murmur" in your present issue, so that some seemingly simple cases might be really complicated by cardiac conditions.

I am, Sirs, yours faithfully,

A. D. LEITH NAPIER, M.D.

Beaufort-gardens, S.W., Oct. 13th, 1887.

"IS CANCER CONTAGIOUS?"

To the Editors of THE LANCET.

SIRS,—I have read with interest the annotation in your issue of the 8th inst. (p. 727) and Dr. Adam's letter published to-day (p. 766). If cancer were a contagious disease—using the term in its ordinary sense—such examples as those now cited would be very common instead of very rare. There is little doubt that cancer may be reproduced by direct implantation of small portions of the growth upon a suitable nidus (grafting). And the difficulties which attend the conditions essential to this method of propagation is the explanation of the rarity of the phenomenon. Mr. Hutchinson jun. related to me an instance in which a cancerous growth appeared upon the back of the hand, presumably caused by the implantation thereon of a portion of a similar growth from the patient's face. That the glans penis might become the seat of cancer from direct implantation of cells from a cancerous cervix uteri is possible, but the few examples recorded of penile and uterine cancer in man and wife, considered with the rarity of cancer of the penis and the great comparative frequency of uterine cancer, strengthens my belief that if it ever be directly transmitted from one to another individual, the passage of cancer is effected by grafting—the process being comparable to the well-known surgical method of skin grafting. Therefore the interesting case of a member of our profession who, with his two wives, died of cancer, as described by Dr. Adam, should be regarded as a remarkable *coincidence* only. I am, Sirs, your faithful servant,

CHAS. E. JENNINGS, F.R.C.S. Eng.

Upper Brook-street, Grosvenor-square, W., Oct. 15th, 1887.

To the Editors of THE LANCET.

SIRS,—With reference to the question of the contagiousness of cancer, I can mention two cases which somewhat bear out the idea of the possibility of such an occurrence.

In 1883 a man was admitted into the Liverpool Infirmary suffering from epithelioma of the penis. He stated that his wife had died some time before of cancer of the womb, and he thought his complaint was something which he had contracted from her. He had never had any venereal disease. I can distinctly recall to mind the remark of the surgeon whose case it was, that we had no evidence that cancer could be so communicated.

The second case occurred in my practice a few months ago. In March, 1887, I was called to Mrs. E——, and found her suffering from uterine cancer, which had evidently been in existence at least some months; it being, in fact, too late then for any operative interference. This woman's husband had had his entire tongue removed for epithelioma in November, 1885. Both she and her friends were quite unaware of anything being wrong with the uterus. The cancer subsequently grew very rapidly, and she died in July last. The family history on both sides was good.

I am, Sirs, yours obediently,

THOS. G. LASLETT, L.R.C.P. Lond., &c.

Farnworth, Bolton, Oct. 19th.

THE SMALL-POX OUTBREAK IN THE PERTH INFIRMARY.

To the Editors of THE LANCET.

SIRS,—So much has been said and written about the recent outbreak of small-pox in the infirmary here, that it appears due to ourselves, our medical brethren, and the public to send you a short statement of the occurrence, and how it has been dealt with.

The disease showed itself in three female patients lying in the same ward at the beginning of this month. The medical officer in charge, while suspicious as to the nature of the affection and alive to the danger, was not quite sure of the diagnosis. On the 4th, a consultation of the staff was held, and suspicions fully confirmed. The local authority were informed of the outbreak, but their hospital was not in a fit state to receive patients. These were removed the following night, and even then cleaning and other work were still in progress. Next day three nurses were evidently attacked, and another female patient, who had been lying in No. 1 ward, showed suspicious symptoms. Immediate action was necessary. Women only had been seized, but men might be any hour. The outbreak was a mystery, its future uncertain. A large detached building, erected in 1865 for infectious diseases, was seen to be available, and the sufferers were at once taken there. No. 1 (the ward affected) had been cleared of all patients not down with the disease on the day of its discovery, and thoroughly disinfected. All mattresses that had been in the ward were burned, bedding at once steeped in 1 in 20 carbolic acid, then boiled, and afterwards washed. One other nurse was seized with suspicious symptoms eight days after assisting in the removal of her colleagues to the west wing; and a fourth female patient was also attacked, and she too was at once taken there. We are quite satisfied that she has passed through an attack of small-pox, but so extremely mild—eruption only two or three aborting vesicles—that no one would have been justified in sending her to any hospital outside that in which she was serving. Fortunately for such a

Digitized by Google

case, our infirmary has always had abundant available space for complete isolation. Three detached blocks provide accommodation for over 100 patients; very seldom fifty, rarely more than forty, patients are in the house at one time. Small-pox nurses were at once obtained from Edinburgh, and the most rigid quarantine enforced.

We were not prepared for such an occurrence; but this only led to a little extravagance in burning bed and body linen instead of washing it. There is a small kitchen belonging to the building, but no trustworthy cook could be had at a moment's notice. All food required, beyond what the nurses could prepare, has been taken to the door and placed in suitable vessels which never leave the infected building. The disease has not spread, and there is every reason to hope that it has been stamped out.

We are, Sirs, yours truly,

DAVID H., STIRLING, M.D.,
Consulting Physician and Surgeon, County and City of Perth Infirmary.
JOHN T. GRAHAM, M.D.,
Visiting Surgeon, ditto.
LEIGH HUNT, M.B.,
Visiting Officer, ditto.

Perth, Oct. 25th, 1887.

VACCINATION AND REVACCINATION.

To the Editors of THE LANCET.

SIRS,—In connexion with the interesting discussion in your columns on the subject of vaccination, I have had a personal experience which perhaps you may consider worth publishing.

I was at a boarding school where there were about 160 pupils. Small-pox appeared; how it made an entry was never very well cleared up. Within about a week thirteen boys became ill, and at the end of that time I myself became so unwell that I was no longer able to keep to my feet, and was removed to that part of the College called the "infirmary," where the thirteen were already isolated. On the same evening everyone—boys masters, and servants, with the exception of those who had been successfully revaccinated or had previously had small-pox—was vaccinated. Whether all these vaccinations proved successful I cannot say. The result, however, I can answer for. Not another case of small-pox occurred from the moment of this general vaccination, although the rest of the 160 boys were subject to exactly the same influences as the fourteen who were attacked, *excepting the revaccination.* Of the fourteen, one died, and the remaining thirteen were all more or less badly marked about the face. I may mention that I had never been revaccinated, and the mark that remained from my first vaccination was scarcely perceptible. This experience has very strongly impressed me with the importance of vaccination or revaccination, as the case may be, even when small-pox has already appeared in a house.

I am, Sirs, yours truly,

ALFRED J. MACNALLY, B.A., M.B., &c.

Kingstown, Oct. 22nd, 1887.

TREATMENT OF SCARLET FEVER.

To the Editors of THE LANCET.

SIRS,—I have for some years treated all my scarlet fever cases with, in addition to the ordinary treatment by salines, an application every day of 1 in 20 carbolic oil to the whole of the surface of the body. By this means I have always been able to prevent the disease attacking others in the house, and I have noticed that all cases so treated from the beginning have done well. After the letter of Mr. Arthur Wiglesworth in your paper it occurs to me that the carbolic acid was in part absorbed, and was an important agent in the well-doing of my patients.

I am, Sirs, your obedient servant,

ALBERT BENTHALL.

Southsea, Oct. 14th, 1887.

SPANISH CONGRESS FOR THE PROTECTION OF YOUNG CHILDREN.—A Congress for the Protection of Young Children has recently held some meetings in Cadiz. The questions discussed included the establishment of hygienic schools with medical men as masters, the necessity of modifying the present system of education, the insufficiency of the support allowed by the State for children, and the regulation of the employment of children in factories and workshops.

MANCHESTER.

(From our own Correspondent.)

OWENS COLLEGE.

THE Medical Societies have commenced work again for the winter. On the 12th inst., at the Pathological Society, Mr. Stocks was elected president for the coming year. In addition to the usual pathological exhibits, Dr. Dreschfeld gave a very interesting *résumé* of some experimental work he has been doing, bearing upon the bacterial origin of malignant endocarditis. He concludes that a streptococcus associated with this disease is the true pathogenic organism producing it. The Medical Society held its first meeting on Wednesday last, when several good surgical cases were exhibited. The entries at the College, though not yet complete, show that Owens will again take the lead of the provincial medical schools, and probably not more than two or three of the metropolitan schools will exceed it in numbers. More than ninety students have been entered, of whom seventy have entered for the whole curriculum. Professor Young, the Dean, in his annual report, states that, "while there has been no diminution in the number of those presenting themselves for the degree of the University of London, the number of candidates for the Victoria University degree has largely increased." The appointment of Dr. Ross as joint lecturer on medicine with Dr. Morgan has given much satisfaction to the students. Sir Wm. Roberts and Sir H. Roscoe have been appointed Emeritus Professor of Medicine and of Chemistry respectively. It is in contemplation to present to Sir Hy. Roscoe his portrait, as a token of respect and admiration from those who have been students under him in days gone by. Subscriptions will be received from any old "Owens man" by Dr. Thorpe, Science and Art Department, South Kensington.

THE EXHIBITION.

The success of our Jubilee Exhibition has been unparalleled, considerably more than four millions of persons having visited it. If any of your readers in this district have not examined the beautiful specimens of rare chemicals, alkaloids, and other allied substances, they will do well to do so ere the Exhibition closes. Space will only permit the bare mention by name of the beautiful cinchona alkaloids and barks shown by Messrs. Howard. Lactic acid (sp. gr. 1·21), for use as a caustic, nitrate of aconitine, hydrochlorate of apomorphine, pure atropine, berberine, salts of cafferine, camphor monobromide, tannate of cannabine, chrysarobin, salts of cocaine, colchicine, hydrastine, hyoscyamine, and many other rare and interesting active principles, are shown by Messrs. Merck; whilst Messrs. Christy and Co. have a large collection of the raw vegetable, plant, fruit, &c., from which many of the foregoing are obtained. The chemical student will be interested in the rare metals, selenium and its salts, tellurium, cermanium, indium, gallium, &c., shown by Dr. T. Schuchardt of Germany.

ACCOMMODATION FOR INFECTIOUS CASES.

The proposal to erect a new fever hospital at Hope on ground belonging to the Salford guardians has been vetoed by the Local Government Board, so the corporation will have to look elsewhere for a site. Seeing how large an open space exists at Monsall, where all small-pox cases from Salford are at present treated, it seems a pity that arrangements cannot be made with Manchester to receive all other infectious cases too. Owing to the continued prevalence of scarlet fever, the Monsall hospital has had considerable difficulty in finding room for all the patients admitted there, the total number under treatment at the present time being the largest since the hospital was established. Happily we have but little small-pox, but, seeing how frequent and extensive the communication with Sheffield is, where small-pox is now rife, it will not be surprising if more cases are met with.

If the ship canal scheme has done nothing else, it has wakened up our municipal authorities to take immediate steps to stop the pollution of the Irwell by sewage. Manchester is not only about setting her own house in order, but is taking energetic steps to compel all other offenders to do likewise.

Among the candidates for municipal honours at the ensuing elections for city councillors is one representative of the medical profession. Manchester at present, unlike

Digitized by Google

the neighbouring borough of Salford, has no medical man on its Council. A member of our profession would undoubtedly be of considerable service in many departments of corporation work.

Manchester, Oct. 24th.

LIVERPOOL.

(*From our own Correspondent.*)

THE LIVERPOOL MEDICAL INSTITUTION.

THE opening of the forty-ninth session of the Liverpool Medical Institution took place on the 6th inst., when the president, Dr. J. Birkbeck Nevins, delivered the inaugural address. The subject was the sanitary arrangements of four large communities differing widely from one another. These latter were, the camp of the Israelites, Edinburgh, Manchester, and Liverpool. The address was accompanied with illustrations, and was listened to most attentively by a large audience.

THE ROYAL SOUTHERN HOSPITAL.

A vacancy having been caused by the resignation of Dr. Little, one of the surgeons of the Royal Southern Hospital, Drs. Rawdon and Alexander were candidates until recently, when the latter gentleman retired in favour of Dr. Rawdon, who was elected without opposition on the 24th inst. Dr. Rawdon is well and favourably known for his assiduous services as surgeon to the Infirmary for Children, which office he has held for fifteen years past. There will be another vacancy shortly in the surgical staff, to which Dr. Wm. Alexander, visiting surgeon to the Liverpool Workhouse, author of the Jacksonian Prize Essay of 1881 and of the Sir Astley Cooper Prize of 1883, will most probably be elected without opposition.

THE CITY HOSPITALS FOR INFECTIOUS DISEASES.

For some time past the question of providing the necessary hospital accommodation for infectious diseases has been the subject of much discussion, not unattended with acrimony. Formerly provision was made by the parochial authorities of Liverpool, West Derby, and Toxteth, but this being found to be contrary to law, different arrangements had to be made. On the recommendation of the Hospitals Committee, of which Mr. Robert Hamilton (senior surgeon to the Royal Southern Hospital) is chairman, the Netherfield-road Hospital, which had been presented to the city by its former managers, was altered, and fitted up at a cost of £22,000, provision being made in it for eighty beds. The Grafton-street Hospital was also commenced, the accommodation to be seventy-two beds and the cost £41,800, which it is believed will be greatly needed. It will be absolutely necessary to provide a further number of 186 beds if we are to deal satisfactorily with an epidemic of scarlatina such as is now raging in London, and might at any time break out in Liverpool. Of course the cost of the latter must depend upon the site, and the City Council at their next meeting will have before them two alternative plans, one estimated to cost £62,800, the other £101,246. To most medical readers these figures will appear excessive, while those who have had experience of hospitals of this class will know that the expenditure of so large a sum is not justifiable. The original suggested scheme of Dr. Taylor, the medical officer of health, was to have a small permanent hospital, with additional temporary removable wards, to which, however, Mr. Hamilton was opposed. The present juncture is a very serious one; means of isolating cases of fever are urgently needed, but a judicious expenditure of public money is also necessary.

Liverpool, Oct. 26th.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.

THE foundation stone of the new building for the University of Durham College of Medicine, erected from the designs of Messrs. Dunn of Harvard, is to be laid on next Wednesday, Nov. 3rd, by the Duke of Northumberland. The buildings have been in progress for some time, but the foundation-stone ceremony has been unavoidably delayed. This is a pity, as the season is rather advanced for the business. The new College is situated in Bath-road contiguous to Northumberland-street, one of the principal streets of the city. The building, at the same time, is a considerable distance from the Royal Infirmary; but there can be no doubt, in the growing state of the city, the infirmary itself must soon shift its quarters, and it is more than probable that it will also follow in the direction of the Medical School. The anatomical block, it is hoped, will be ready for occupation in January next, and the remaining portion in October, 1888. The buildings will be erected round a central quadrangle, the anatomical block forming the east side; the chief entrance, examination hall, and museum in front; and the residential college the west side. The south side, intended for the extension of the departments of physiology and pathology, will not for the present be erected. The style adopted is Elizabethan. The mullioned windows are carried out in stone, and the walls and dressings in red brick and terra cotta. The anatomical block contains a dissecting-room, 70 ft. long by 30 ft. wide, lighted from the north side by a ridge and furrow roof, and floored with asphalte, so as to be clean, noiseless, and warm under foot. A large locker room and lavatory adjoining are similarly floored. Near by is the anatomical theatre, lighted from above and fitted with special apparatus for demonstration purposes, and the professors' private room. Above is the bone room and curators' work room. Below is a summer dissecting room, a couple of rooms for the department of comparative anatomy, anatomy, and animal pathology, a mortuary injecting room and preparation room, with the heating vaults, &c. There is a large yard, with accommodation for animals suffering from disease. All the interior walls of the block are lined with white glazed bricks. The ventilation is provided for by heated shafts; for warming, hot water coils are fitted throughout. The main front contains the arched entrance centrally under a square tower with oriel windows corbelled out above the archway, and leads through a vestibule to the hall and staircase. Rooms for the registrar and porter are on the right and left. The ground-floor is occupied by the council room, a materia medica room, a smaller lecture theatre, with a dark room attached, professors' rooms, and offices. A spacious oak staircase, with double flight of steps, leads to the upper floor, which contains a library and examination hall, 80 ft. by 35 ft.; and the museum, 60 ft. by 35 ft. The former is of Elizabethan design. In the tower is a smoking room for students.

SUNDERLAND.

The young ladies of Sunderland have held a very successful bazaar in aid of the new Hartley Wing of the Sunderland Infirmary. The bazaar was opened under good auspices, and carried out with spirit.

ALNWICK.

The annual meeting of the Alnwick Infirmary has been held, and the report presented the usual features, with the exception that there had been an increase of 100 in the number of out-patients, owing to an epidemic of measles. The financial position of the infirmary had improved, due, it was said, in a great measure to the judicious and economical management of the matron and the house-surgeon, Dr. A. Scott Purves.

Newcastle-upon-Tyne, Oct. 26th, 1887.

EDINBURGH.

(*From our own Correspondent.*)

THE UNIVERSITY COURT.

AT the last meeting of the University Court a good deal of important business was transacted. A question which has been pending for several months was provisionally settled by the legal opinion of two leading members of the Scottish Bar. This was the question as to which body in the University has the right to elect the representative of the University in the General Medical Council. At the last meeting of the University General Council, composed of Edinburgh graduates, it was claimed that to that body the right really pertained, as representing the University in its widest sense. This was combated by representatives of the Senatus at the last

Digitized by Google

General Council meeting, and finally the matter was submitted for decision to the University Court. As they felt a difficulty in giving an opinion on the exact tenour of the provisions of the Universities (Scotland) Act, 1858, dealing with this point, they retained the services of the Dean of the Faculty of Advocates (Mr. Mackintosh) and the Solicitor-General for Scotland (Mr. J. P. B. Robertson). These gentlemen have now presented their finding in the matter; which is that inasmuch as prior to the Act of 1858 the Senatus was the executive body in the University, and since that Act in no way curtailed the executive powers of the Senatus, the duty of electing this representative lies still with them: in no case could this function lie with the General Council, whose office in the University polity is a purely deliberative one. This opinion will probably settle the question for the present, which is in itself a satisfactory result of the discussion; it will probably do good also in drawing the attention of graduates to this and several similar features in the Universities' system that might well be modified in any legislation that may be proposed on the subject, with the object of increasing their voice in the conduct of University affairs. This finding of counsel will be formally reported to the General Council meeting a few days hence, and will probably prove a not very pleasant pill to the democratic element, which is now strongly developed in its constitution. The Court then proceeded to consider some arrangements for teaching in the present session. They confirmed the leave of absence granted to Professor William Rutherford for a further period of six months, and approved the arrangements by which Professor Haycraft will carry on the work of the department during the winter session. The Court also recognised the course of lectures by Dr. D. Noël-Paton at the Royal College of Surgeons as a qualifying course for students attending the University medical curriculum. At the same time the course of demonstrations on Practical Pathology, by Dr. William Russell, was recognised as a qualifying course.

Edinburgh, Oct. 25th.

ABERDEEN.

(From our own Correspondent.)

THE UNIVERSITY.

THE winter session at Marischal College was opened on Wednesday, the 19th inst., when several of the professors delivered introductory lectures. Dr. Struthers chose for his text Recent Medical Legislation, and Dr. Hamilton gave a most interesting lecture on the Transmission of Scarlet Fever and Tuberculosis from the Cow to Man. Professor Cash was introduced to his class on Friday by Principal Geddes, and delivered an able address on Pharmacology and Therapeutics.

THE STUDENTS AND CLINICAL TEACHING.

The students are indignant, and justly so, to find that during the vacation changes have been made in the visiting hours at the Royal Infirmary, which not only limit the time for work at the General Dispensary to less than an hour, but deprive them altogether of the opportunity of taking advantage of the clinical material to be found in the out-patient department and wards of the Hospital for Sick Children. This is surely a great mistake, for anyone who knows the Aberdeen Medical School must acknowledge that the students have always asked, not for less, but for much more clinical work and teaching; and if this new arrangement be continued, a great many of the students will undoubtedly in future spend their fourth year at the Edinburgh and other schools.

HEALTH OF THE CITY.

For the month of September the health of the city was most satisfactory, and, on the whole, it continues to be so, but, unfortunately, we are threatened with an epidemic of scarlet fever. At a meeting of the Sanitary Association of Scotland, recently held at Falkirk, Mr. Cameron, sanitary inspector for Aberdeen, read a paper giving an account of the sanitary work carried out in the city during the last ten years or so. He pointed out that Aberdeen was exceptionally fortunate with regard to its sanitary legislation. Under the Aberdeen Corporation Act for 1881, all new dwelling-houses must have a certain amount of air space at the rear, as well as a prescribed open space in the front, and the rooms must be at least nine feet high. In all new houses and houses undergoing alteration no drains or pipes are allowed to be covered in after they are laid until the smoke test has been applied by the inspector. Then, again, by another clause of the Act medical practitioners are bound to report to the sanitary authorities within twenty-four hours all cases of infectious disease. As a proof of the amount and nature of the work done by the sanitary staff, Mr. Cameron referred to his last annual report, where it is stated that "during the year 2885 nuisances were removed, 3954 notices issued, 568 patients removed to the hospital, and 1532 patients supervised at their homes; 27,000 lb. of meat seized, and over 1900 visits made to cow-sheds, dairies, and milkshops." During the five years 1882-1886 the Town Council had spent in connexion with the health of the city £9281, the amount increasing yearly from £1332 in 1832 to £3041 in 1886, and during the present year £1100 was spent on an addition to the City Hospital, which originally cost £14,000. As a result of all this expenditure &c., Mr. Cameron said that we now have comparative immunity from the ravages of infectious diseases, while the death-rate has fallen from an average of 23·68 per 1000 for the five years 1869-1873, to 19·87 for the three years 1884-1886; and for 1885 the unusually low death-rate of 17·94 per 1000 was recorded. Another striking result is the great decrease in the number of cases of typhus fever, of which in 1882 there were 111 cases; in 1883, 26; 56 in 1884; 11 in 1885, and only 1 case in 1886.

DUBLIN.

(From our own Correspondent.)

CORPORATION GRANTS TO THE DUBLIN HOSPITALS.

AT a meeting of the Dublin Town Council last Monday a sum of £4000 was voted in aid of the Dublin Hospitals. A recommendation of the Finance Committee to the Council that the grants be reduced to £3000 was lost. The Rotundo Lying-in Hospital, which receives only £200, was struck out because the Protestant governors outnumbered the Roman Catholic. As one of the Council very properly pointed out, the Corporation are dispensers of the public funds, and they ought not to allow theological questions to influence them in the matter. I may add that nineteen out of twenty of the inmates of that excellent and well-managed institution, the Rotundo Lying-in Hospital, are Roman Catholics, and it would be as unjustifiable an act on the part of the governors if they refused admission to the hospital of any patient belonging to that religious community.

ROYAL UNIVERSITY OF IRELAND.

Dr. Macswiney has been elected a Fellow in the Department of Medicine. Mr. Walter E. Adeney has been appointed to the vacant curatorship. The Senate have determined to refuse to accept certificates of night lectures, save in the case of medical students registered as such prior to Oct. 1st, 1887, and for lectures attended by them prior to July, 1889.

APOTHECARIES' CONJOINT SCHEME.

On November 4th the governors of the Apothecaries' Hall will elect an Examiner in Practice of Medicine under the Conjoint Scheme between it and the Royal College of Surgeons in Ireland. Candidates for the post must be hospital physicians of at least five years' standing.

SCHOOL OF PHYSIC, TRINITY COLLEGE, DUBLIN.

The introductory address at the opening of the new Medical School Buildings will be delivered by the Rev. Dr. Haughton, F.R.S., on Tuesday next, November 1st.

DUBLIN HOSPITAL SUNDAY FUND.

The annual collections in aid of the Dublin hospitals will be held on Nov. 18th, when collections will be taken up in the various churches in and adjacent to Dublin for this most charitable object. Every denomination, including the Jewish, take part in the good work, with the exception of the Roman Catholic Church, whose members, for some unexplained reason, have hitherto refused to co-operate, although the vast majority of the poor treated in the Dublin hospitals belong to that community.

Dublin, Oct. 25th.

PARIS.

(From our Paris Correspondent.)

MORPHINOMANIA.

THE post-mortem examination of the bodies of subjects dying from morphinomania is rarely published, so that the following note, which was read by Professor Ball at the meeting of the Academy of Medicine last week, may be of some interest. The author related the case of a patient, a young girl aged sixteen years, who was admitted into the Ste. Anne Asylum in the month of May last, and had gone thither to place herself under treatment with the view of being cured of her pernicious habit, which she contracted from the age of twelve years for the relief of pains attending fissure of the anus. At the time of her admission to the Asylum she used to inject subcutaneously from one to two grammes of the hydrochlorate of morphia per day, and, according to her own desire, an attempt was made to immediately suppress the injections, but on the third day she was seized with such alarming symptoms that Dr. Ball was induced to resort to the hypodermic injections, gradually diminishing the dose of the morphia to only one centigramme per day. To combat the insomnia and agitation which the patient was labouring under, enemata of bromide of potassium and chloral were administered at bedtime, and sulphate of sparteine was injected subcutaneously for the relief of the cardiac symptoms. The treatment lasted forty-two days, and on July 10th the suppression of the morphia was complete, and the patient's health seemed satisfactory. On the morning of the 23rd, however, she was suddenly seized with hysterical and syncopal symptoms, and in a few hours she expired. At the necropsy, the heart was found to be loaded with fat, but there was nothing of any note observed in the other organs. On chemical examination, however, traces of morphia were manifest in the kidneys, spleen, and liver, as well as in the nervous centres. These organs contained an appreciable quantity of morphia, though this result is opposed to the results obtained by the greater part of the authors who have investigated this subject; but after what has been observed in the present case, it appears evident that morphia may sometimes remain a long time in the tissues after having penetrated into the economy, and the presence of this poison in the organs may explain by a sort of auto-intoxication the tardy accidents which are sometimes observed in morphinomaniacs long after the cessation of the abuse of the drug. This would explain how patients of this category succumb in a state of collapse several days after apparent cure. Professor Ball concluded his paper with the remark that, independently of all hypothesis, one practical conclusion may be deduced from the above facts—viz., that cardiac tonics play a most important part in the treatment of morphinomania, and that it is absolutely indispensable to administer either sparteine or some other cardiac medicament, not only during the gradual suppression, but a long time after the complete discontinuance of the drug. Moreover, these facts demonstrate the danger resulting from the sudden withdrawal of the morphia, for if the gradual suppression can of itself expose the patient to serious dangers, it is all the greater reason why the sudden suppression heretofore in vogue should be proscribed.

SMALL-POX HOSPITALS AND INFECTION.

A short time ago a hospital for variolous patients was erected at Aubervilliers, just outside the fortifications of Paris. At a short distance from this place, but within the fortifications, is situated extensive gasworks at La Villette, one of the most populous districts of Paris. Dr. Créquy, a physician practising in that district, in a report read before the Academy of Medicine last week, has drawn attention to the dangers of the proximity of such a hospital to so populous a part of the city, for at the gasworks above referred to there are 1200 workmen employed in summer and 2000 in winter, who, with their families, reside in the neighbourhood of the works. Since the establishment of this hospital several cases of small-pox have occurred among this population, which Dr. Créquy thinks cannot be attributed to any other cause than "contagion at a distance," which in English medical literature would be expressed by the term infection. In the interest of public health, he would therefore demand the closing of this hospital as soon as possible and its removal to some other quarter. He does not pretend to fix the distance at which these hospitals for infectious diseases can be safely established from dwelling houses, but an idea may be formed by considering the distance at which the small-pox hospital at Aubervilliers is situated from La Villette—viz., 230 metres. On the same grounds the author objects to the too-short distance existing between the wards for isolating patients and the main building, which in some hospitals is only 100 metres.

TANACETIC RABIES.

In my letter of last week I communicated a note read by M. Peyraud at the Academy of Sciences on "tanacetic rabies," which the author has also submitted to the Academy of Medicine through Professor Hayem. The note need not be reproduced here, but I may mention that Professor Hayem, in presenting the paper, remarked that in endeavouring to ascertain whether this tanacetic rabies was contagious, his experiments led him to conclude in the negative. He, moreover, observed that he had reason to believe that tanacetic and true rabies had the same antagonist—viz., chloral. M. Colin, the well-known veterinarian, made the remark at the same meeting that there are a certain number of substances besides tanaisia susceptible of determining symptoms similar to those observed by M. Peyraud. According to M. Colin, the symptoms observed are due to a simple excitation of the bulb, and rabies has nothing to do with the tanacetic malady.

Paris, Oct. 25th.

ROYAL COLLEGE OF PHYSICIANS.

A COMITIA of the Fellows of the College of Physicians was held on the 27th inst., Sir W. Jenner, Bart., K.C.B., President, in the chair.

Dr. C. W. Marriott was admitted to the Membership of the College.

A communication from the Colonial Office was read, thanking the College for its memorandum upon the Contagiousness of Leprosy, and stating that any suggestions which the College might make for the further investigation of the subject would, if possible, be carried out. In another communication the Colonial Office forwarded to the College a copy of the report on Cerebro-spinal Meningitis in the Island of Gozo, which had been sent by the Governor of Malta.

Letters were read from the Council of the Sanitary Institute of Great Britain asking the co-operation of the College in the proposed International Sanitary Conference to be held in London in 1890.

Sir E. Sieveking, on behalf of the treasurer, presented the quarterly report of the Finance Committee. It contained a recommendation to the effect that the windows of the staircase in the College building be filled with the armorial bearings of past presidents. The report was adopted, and a committee, comprising the members of the Finance Committee, together with Dr. Munk, was nominated to carry the proposal into effect.

Sir H. Pitman was re-elected a member of the Committee of Management; and the nomination by that committee of Drs. Stevenson, Ballard, Thorne Thorne, and Corfield as examiners for the diploma of Public Health was approved.

Another report from the same committee, requesting that a clause of a previous report, which recommended the recognition of clinical study at the Leeds Hospital for Women and Children, might be cancelled, was also adopted after some discussion.

The President nominated Sir E. Sieveking and Dr. Handfield Jones to be vice-presidents for the ensuing year.

THE HOSPITALS ASSOCIATION.—This Association, according to its third annual report, appears to be attracting considerable support. The scheme propounded by Sir Andrew Clark for increasing the funds of the hospitals is being brought under the notice of the ministers of all denominations and of the representatives of other bodies. The second evening meeting of the fifth session of the Association will be held at the Board-room of the Middlesex Hospital on Nov. 9th, at 8 P.M. Sir Douglas Galton, K.C.B., will preside, and a paper will be read by Mr. Keith D. Young, F.R.I.B.A., on Hospital Construction, to be followed by a discussion.

Obituary.

HAROLD GILBERTSON TAYLOR, M.D. LOND.

BY the death of Dr. Harold G. Taylor, which occurred at the Royal Albert Asylum, Lancaster, of which institution he was assistant medical officer, on the 16th inst., at the early age of thirty-two, a career of much promise and usefulness was suddenly terminated, to the deep regret of his many friends.

Dr. H. G. Taylor was the second son of Dr. John Taylor, a physician who was for many years in practice at Bayswater; and after having received his general education at the University College School he chose to follow his father's profession, and became a medical student at King's College, London. Here he passed through his curriculum with distinction, gaining the Jelf medal and many other college prizes, and in 1879 he graduated M.B. at the University of London, taking honours in medicine and obstetrics, and the gold medal in forensic medicine. He served the office of house-physician at King's College Hospital, and was subsequently appointed house-surgeon to the Portland Town Dispensary. In 1880 he applied for, and obtained, the post of assistant medical officer to the Royal Albert Asylum for Idiots and Imbeciles of the Northern Counties, Dr. Shuttleworth being the medical superintendent. In this position Dr. Taylor's qualities of careful observation, unfailing patience, and exemplary kindness were invaluable in the daily routine of his duties, whilst his scientific attainments enabled him to take an interest in his work of more than routine character. He continued to hold the appointment until his death, and, in fact, may be said to have died in harness, having from a sense of duty deferred his customary autumn holiday in consequence of the outbreak of an epidemic in the institution. Early in 1886 he had suffered from a brief attack of pneumonia, presumably of glandular origin; but from this he speedily recovered, and apparently regained his usual health. Though not of robust appearance, he seldom seemed to ail anything, and it was only on Oct. 10th that he complained of feeling unwell. Symptoms of inflammation of the right lung soon developed, and, unfortunately, pleurisy and extension of the pneumonia to the left side followed. To this complication he succumbed on the 16th inst. He was attended by his friends, Mr. Christopher Johnson and Dr. Rayne of Lancaster, in consultation with Dr. Shuttleworth.

Dr. Taylor was of a somewhat retiring disposition, but by those who knew him his excellent qualities of head and heart were much valued. He had endeared himself both to the staff and the patients of the asylum by his personal kindness, as well as his professional skill, and the esteem with which he was regarded was evidenced by the numerous wreaths and other floral offerings sent for his funeral, which took place at Lancaster Cemetery on the 20th inst. He was a conspicuous example of devotion to duty, and of thorough conscientiousness in all he undertook.

EVAN EVANS, M.D. LOND.,

STAFF SURGEON, R.N.

THE deceased naval medical officer, who was the eldest son of William Evans, surgeon, of Devonport, and grandson of Evan Evans, surgeon, R.N., was born at Devonport on March 13th, 1821. In 1838 he entered the medical classes at University College, London, and in 1842 passed the L.S.A. and M.R.C.S. In June of that year he entered the navy, and served in H.M.S. *Gorgon* in the operations in the River Parana in 1845 and 1846. For these, and especially for the action of Obligado, he was promoted after only three years' service. Later he was attached to the hospitals of Malta and Chatham. In 1853, while still on active service, he passed the M.B. Lond., and in 1855 the M.D. In 1855 he retired from active service and commenced practice in London. Here for more than thirty years he carried on a very extensive practice; but in January, 1886, on recovering from a severe attack of pneumonia, he found it necessary to restrict his work considerably, and at the commencement of this year he was compelled to relinquish it entirely. It was hoped that perfect rest might restore him, at least partially, to health; but it was found that he slowly grew weaker, and on the evening of Monday, the 17th inst., he died, at the age of sixty-six years. All who knew him will bear witness to his single-hearted devotion to his practice, to which one cannot but think he ultimately sacrificed his life.

Medical News.

COLLEGE OF PHYSICIANS IN IRELAND.—At the October examinations the following obtained licences in Medicine and Midwifery:—

MEDICINE.—William Henry Carrington, Henry Thomas Hamilton.
MIDWIFERY.—Henry Thomas Hamilton.

The undernamed have been admitted Members:—

George Plunkett O'Beirne; Stewart Frazer Hamilton, Staff Surg. R.N.

At examinations held in August the following were admitted Licentiates in Medicine and Midwifery:—

MEDICINE.—Thomas Richard John Cowen, William Cremin, Edward Frazer, Eugene Glynn, Richard Joseph Hewitt, Richard Jones, Peter Paul Keane, John Joseph McNabol, Joseph Francis Mannix, Michael Shanley.

MIDWIFERY.—Benjamin Beamish, Thomas R. J. Cowen, W. Cremin, Edward Frazer, Eugene Glynn, Richard J. Hewitt, Richard Jones, Peter P. Keane, John J. McNabol, J. F. Mannix, Michael Shanley.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—At the annual meeting of this College on Oct. 19th the following office-bearers were elected for the ensuing year:—President: Joseph Bell. Vice-President: D. Argyll Robertson, M.D. Secretary and Treasurer: Robert J. Blair Cunynghame, M.D. Librarian: Archibald Dickson, M.D. President's Council: James Donaldson Gillespie, M.D.; Henry Duncan Littlejohn, M.D.; Patrick Heron Watson, M.D., LL.D.; Francis Brodie Imlach; John Smith, M.D., LL.D.; Thomas Annandale; D. Argyll Robertson, M.D. (*ex-officio*); and A. J. Blair Cunynghame, M.D. (*ex-officio*). Representative in General Medical Council: Patrick Heron Watson, M.D., LL.D. Examiners: James D. Gillespie, M.D.; Henry D. Littlejohn, M.D.; Patrick H. Watson, M.D., LL.D.; David Wilson, M.D.; John Smith, M.D., LL.D.; Joseph Bell; John Duncan, M.D., LL.D.; Robert J. Blair Cunynghame, M.D.; Alexander G. Miller; Peter H. Maclaren, M.D.; Johnson Symington, M.D.; Francis Cadell; James Dunsmure, M.D.; William Craig, M.D.; and Charles E. Underhill, M.B. Dental Examiners: Patrick H. Watson, M.D., LL.D.; Henry D. Littlejohn, M.D.; David Neilson, M.D.; John Smith, M.D., LL.D.; Andrew Wilson, L.D.S.; and Geo. W. Watson, L.D.S. Assessors: Archibald Inglis, M.D.; Sir William Turner; Francis B. Imlach; and D. Argyll Robertson, M.D. Conservator of Museum: Charles W. Cathcart, M.B.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—The following gentlemen have been elected the office-bearers of this Society for the ensuing session:—President: Professor T. M'Call Anderson. Vice-Presidents: Dr. D. C. M'Vail, Dr. Alexander Patterson, Dr. Joseph Coats, Dr. James Stirton. Council: Dr. S. Gemmell, Dr. J. W. Anderson, Mr. A. E. Maylard, Dr. D. N. Knox, Dr. Alexander Robertson, Dr. William M'Ewen, Dr. Edward Macmillan, Dr. A. Wallace. Treasurer: Dr. Hugh Thompson. Secretaries of Sections: Dr. George S. Middleton, Dr. John Barlow, Dr. T. K. Dalziel, Dr. T. F. Gilmour. General Secretary: Dr. William G. Dun.

NEW CHILDREN'S HOSPITAL FOR BERLIN.—A large plot of ground in the See Strasse, Berlin, has been granted for the erection of a new children's hospital.

TRICHINOSIS IN BRUNSWICK.—Although some 200 persons have been suffering from trichinosis in Brunswick, no fatal case has occurred. The epidemic is, it is hoped, now over.

NEW HOSPITAL IN MOSCOW.—The foundation stone of a new building for the University Hospital in Moscow was laid last month; more than 2,000,000 roubles (£200,000) are to be spent on its erection.

BIRMINGHAM MEDICAL MISSION.—The twelfth annual meeting of the subscribers to this Mission was held on the 20th inst., when it was reported that the year began with a balance in hand of £38 and ended with a deficiency of £26. The total receipts had amounted to £137. The number of patients seen at the Mission was 3674, and 350 sufferers had been visited at their own homes.

Digitized by Google

GUY'S HOSPITAL UNIVERSITIES' CLUB.—The annual dinner of this club will take place at the Holborn Restaurant on Monday, Nov. 21st, at 7.30 P.M. Old Guy's men, belonging to either Oxford or Cambridge University, who may wish to be present, should notify the same to Mr. A. S. Taylor, Guy's Hospital. Prof. Reinold, F.R.S, will occupy the chair.

THE DRAINAGE OF NORWICH.—The Norwich Town Council, which some years ago expended a sum approaching £200,000 in the construction of sewerage works for carrying off both surface water and sewage proper, decided on the 19th inst. to construct a separate system for the sewage at a cost of £78,000. The present system is rendered defective by the enormous influx of spring water into the low-level sewer. The irrigation system is to be continued, and the old service of pipes will be used for surface water.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The following is the list of officers for session 1887-88:—President: Mr. Keetley. Vice-Presidents: Dr. Campbell Pope, Dr. Alderson, Dr. Owles, and Mr. Gunton Alderton. Council, Mr. Barnes, Mr. Hemming, Dr. Thudichum, Dr. Wells, Mr. R. F. Benham, Dr. Pickett, Mr. Lloyd, Dr. Schacht, Dr. Travers: Mr. H. Percy Dunn, Mr. Swinford Edwards, and Dr. Bullock. Treasurer: Mr. Lawrance. Secretaries: Dr. Clippingdale and Dr. Abraham. Auditors: Dr. Banning and Mr. Leonard Mark.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—At a Council meeting of this Association, held at their rooms, 3, Bolt-court, Fleet-street, on Oct. 20th, the following resolution was carried: "That the Council, having considered the memorial of the Darlington Board of Guardians, and not being at present in possession of sufficient information on the subject, defer taking action until such times as the necessity for doing so arises." The Council are also of opinion that alterations of so sweeping a character need not be feared by either medical or other Poor-law officers.

LITERARY ANNOUNCEMENTS. — A work by Dr. Norman Kerr on Inebriety or Narcomania, dealing exhaustively with its Etiology, Pathology, Treatment, and Jurisprudence, will shortly be issued by Mr. H. K. Lewis. Messrs. Wyman and Sons announce the publication in November of a new illustrated monthly magazine, price fourpence, entitled "Baby, a Magazine for Mothers and those who have the care of Children, being a guide to their Management in Health and Disease." Messrs. Cassell and Company, Limited, announce that with the number just issued the English edition of the *International Journal of the Medical Sciences* will cease to appear.

THE SPANISH CENSUS.—The approaching Spanish census is to be taken on the night of December 31st. Those persons who practise medicine are to state whether they are fully qualified medical men (*medicos*), surgeons, dentists, or bloodletters (*sangradores*). Assistants (*practicantes*) are to state whether they are in a pharmacy or with a doctor, and especially whether they are actually practising. Those who practise medicine, even if they should happen to be from home the night the census is taken, are to put themselves down at their usual residence. Persons who die during the night of the census are not to be mentioned in the schedules; but all born that night are to be included, the words "newly born" being substituted for the name.

THE UNIVERSITY OF MADRID.—On Oct. 1st all the Spanish universities were opened for the winter session. In the Madrid or Central University the chair was taken by Señor Navarro Rodigo, one of the Ministers, a number of celebrated political and learned men, together with a considerable sprinkling of ladies, being present. Strangely enough, those most interested in the sessional work of the University—that is to say, the students—were conspicuous by their absence, the authorities having forbidden them to attend. The address, which has excited a good deal of attention, and has served as a basis for some discussion amongst the professorial staff, was delivered by Dr. Rodiguez Carracido, Professor of Organic Chemistry.

QUEEN'S COLLEGE MEDICAL SOCIETY.—The annual meeting of the above Society was held on Wednesday, October 12th, in the Library of the College. The report amply testified to the increasing interest taken in the meetings, and showed that much good scientific work had been done during the past twelve months. The number of members now amounts to 170, and the average number of attendances at the meetings was 26·4. Although the expenses of last year were unusually heavy, still the financial report possessed a balance in favour of the Society. Dr. Grinling, who as a member has worked most assiduously for the Society since its commencement, was unanimously elected President for the ensuing year. In addition Mr. Haslam was elected Vice-President, Mr. J. Hall-Edwards and Mr. B. W. Housman Hon. Secretaries, and Mr. J. H. Brice Treasurer. The business matters being concluded, Mr. Augustus Clay, the retiring President, delivered an address upon Lateral Curvature of the Spine, which was illustrated by numerous diagrams and highly appreciated.

AT an inquest held on the 19th inst. at Halifax, on the body of a youth who died from injuries received while playing football on the 15th inst., the jury returned a verdict to the effect that deceased was killed by accidentally falling.

INCREASED SEVERITY OF SANITARY LEGISLATION IN ST. PETERSBURG.—The punishment that may be inflicted for transgressing the sanitary laws in St. Petersburg is to be increased to three months' arrest, with a fine of from £15 to £30. On a repetition of the offence, this punishment may be doubled. The punishments for adulteration of food are also to be increased in severity.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—A meeting of the members of this Association was held at Manchester on the 13th inst., when Dr. Sergeant (Bolton) read a paper on the Compulsory Notification of Dangerous Infectious Diseases at Bolton, and the resulting Decrease in the Local Mortality. A discussion followed, in which Messrs. Vacher, Kenyon, and Vernon took part.

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—A meeting of the members of this Association was held at Bradford on the 21st inst., Dr. Hime, President, in the chair. After the transaction of some business of a routine nature, Mr. Morley, architect, was introduced to the meeting by the President for the purpose of giving a description of the recent additions to the Bradford Fever Hospital, and upon the conclusion of his communication a desultory discussion ensued, in which Drs. Cameron, Wilson, Roberts, Britton, and others took part. The reading of a paper on School Hygiene, which had been promised by Dr. Hime, was postponed.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADAM, JAMES, M.A., M.B., C.M., has been appointed House-Physician to the Western Infirmary, Glasgow.

ANDERSON, JOHN A., M.B., C.M., has been appointed House-Surgeon to the Western Infirmary, Glasgow.

BOREHAM, FRANK S., L.R.C.P.Ed., L.R.C.S., has been appointed Medical Officer for the Hallaton District of the Uppingham Union.

CARSLAW, JOHN H., M.B., C.M., has been appointed House-Physician to the Western Infirmary, Glasgow.

DAVIES, HUGHES REID, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator to the Fourth District of the Hollingbourne Union.

GERVIS, HENRY, M.D., F.R.C.P.Lond., has been appointed Consulting Obstetric Physician to St. Thomas's Hospital.

HOLLINSHEAD, F., M.R.C.S., L.S.A., has been appointed Medical Officer to the Cottage Homes of the King's Norton Union.

JOHNSTON, ALEX., M.B., C.M. Glas., has been appointed Resident Medical Officer to the Barnes Convalescent Hospital, Cheadle, near Manchester.

LANKESTER, FRANK, L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House-Surgeon to the National Dental Hospital, Great Portland-street, W.

MCLUNNAN, WM., M.B., C.M., has been appointed House-Physician to the Western Infirmary, Glasgow.

NESS, ROBERT B., M.A., M.B., C.M., has been appointed House-Surgeon to the Western Infirmary, Glasgow.

NISBET, ADAM T., M.B., C.M., has been appointed House-Physician to the Western Infirmary, Glasgow.

OLDERSHAW, JOHN, L.R.C.P. Ed., L.R.C.S., has been appointed Medical Officer for the Second District of the Wolverhampton Union.

PATTISON, E. SETON, M.R.C.S., L.R.C.P.Ed., has been appointed Surgeon to the T Division of the Metropolitan Police.

REID, ROBERT G., M.B., C.M., has been appointed House-Surgeon to the Western Infirmary, Glasgow.

ROBERTSON, WM., M.B., C.M., has been appointed House-Surgeon to the Western Infirmary, Glasgow.

SYMONDS, CHARTERS J., M.S., M.D., F.R.C.S.E., has been appointed Surgeon to In-patients to the Evelina Hospital for Children, vice H. G. Howse, M.S., F.R.C.S.E., resigned.

THOMSON, R. STEVENSON, M.D., has been appointed Dispensary Physician to the Western Infirmary, Glasgow.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C. — House-Surgeon.

CENTRAL LONDON SICK ASYLUM DISTRICT.—Assistant Medical Officer and Dispenser. Salary £100 per annum, with board and residence.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Three Clinical Assistants. Fee for a period of three months, £5 5s.

ROTHERHAM HOSPITAL.—Assistant to the House-Surgeon. Rooms, commons, and washing, in lieu of salary.

ROYAL HANTS COUNTY HOSPITAL, Winchester.—House-Surgeon. Salary £100 per annum, with board and lodging.

STROUD GENERAL HOSPITAL.—House-Surgeon. Salary £80 per annum, with board, washing, and lodging.

WESTERN DISPENSARY, Rochester-row, Westminster, S.W.—Attending Medical Officer.

WILTS COUNTY ASYLUM.—Second Assistant Medical Officer. Salary £100 per annum, with board, residence, attendance, and washing.

Births, Marriages, and Deaths.

BIRTHS.

ARCHER.—On the 6th ult., at Moonta, South Australia, the wife of R. Kendray Archer, M.R.C.S., of a son.

BRANFOOT.—On the 26th ult., at Madras, the wife of Surgeon-Major A. M. Branfoot, Indian Medical Department, of a daughter.

REYNOLDS.—On the 19th inst., at Limehurst, Stapleton Hall-road, N., the wife of Frederick Reynolds, L.R.C.P., of a son.

ROBSON.—On the 18th inst., at Walkeringham, Notts, the wife of W. W. C. Robson, M.R.C.S., of a daughter.

SIMON.—On the 17th ult., at Singapore, Straits Settlements, the wife of Max F. Simon, M.R.C.S., L.R.C.P.Lond., Resident Surgeon, General Hospital, of a son.

WELLS.—On the 18th inst., at Douglas, Isle of Man, the wife of Primrose Wells, L.R.C.P.Ed., L.R.C.S., of a son.

MARRIAGES.

CORMACK—FILLET.—On the 25th inst., at the Church of the Resurrection, Brussels, by the Rev. J. Jenkins, Dr. Charles H. Cormack, of Vichy, son of the late Sir John Rose Cormack, to Marie, daughter of the late M. Louis Laurent Fillet, of Brussels.

MACDONALD—MELLIS.—On the 19th inst., at St. Columba's, Pont-street, Belgravia, London, by the Rev. Donald Macleod, D.D., William Burns Macdonald, M.A., M.B., of Dunbar, to Laura, youngest daughter of the late John Mellis, M.R.C.S.Eng., of Fraserburgh, Aberdeenshire.

PRUEN—HUTCHINSON.—On the 22nd ult., at the Mission Church, Frere Town, by the Rev. A. Downes Shaw, assisted by the Rev. H. Binns, of Rabai, both of the Church Missionary Society, and on the 23rd ult., at Zanzibar, by H.B.M.'s Acting Consul-General Major MacDonald (Military Attaché, Cairo), Septimus Tristram Pruen, M.D., M.R.C.S., Church Missionary Society, youngest son of the late Dr. Pruen, of Penang, to Constance Helen (Nellie), second surviving daughter of Surgeon-General J. A. C. Hutchinson, Indian Medical Service, retired.

TUKE—BOGGS.—On the 18th inst., at St. Thomas' Episcopal Church, Edinburgh, by the Rev. E. M. Dawson, Incumbent, assisted by the Rev. W. Magee Tuke, St. Bartholomew's, Winchester, John Batty Tuke, M.B., C.M., M.R.C.P.Ed., of Saughton Hall, Midlothian, to Annie Isabella, fourth surviving daughter of the late Robt. Howden Boggs, of Pencaitland.

WEISS—HOOKE.—On the 19th inst., at St. George's, Hanover-square, by the Rev. S. B. Burnaby, Vicar of Hampstead, Hubert Foveaux Weiss, F.R.C.S.Eng., of 11, Hanover-square, second son of Frederic Foveaux Weiss, to Aris, daughter of E. Hooke, Esq., of Geldard House, Bycullah-park, Enfield.

DEATHS.

EVANS.—On the 17th inst., Evan Evans, M.D.Lond., Staff-Surgeon, R.N., of 63, Finsbury-pavement, and 85, Bethune-road, N., aged 66.

MACGRATH.—On the 7th inst., at 32, Colville-terrace, W., Dr. W. M. MacGrath, aged 46. R.I.P.

ROBERTSON.—At St. Thomas's Home, Lambeth, James Robertson, Staff Surgeon, Royal Navy, aged 47.

ROBINSON.—On the 25th inst., Percival John, youngest child of J. H. Robinson, Surgeon, of Bolton. Deeply regretted.

TAYLOR.—On the 16th inst., at Lancaster, Harold Gilbertsen Taylor, M.D., Assistant Medical Officer of the Royal Albert Asylum, aged 32.

TEEVAN.—On the 22nd inst., at Hawkhurst, after an illness of nearly six years, William Frederic Teevan, B.A., F.R.C.S., late of 10, Portman-square, W., eldest son of the late Wm. Teevan, F.R.C.S., of 23, Bryanston-square, W., aged 58.

THOMSON.—At Kenfield Lodge, Ramsgate, Jn. Buck Thomson, M.R.C.S., aged 77.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, October 31.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. General Meeting. The President, Dr. Hughlings Jackson, will show a patient of his from whose brain Mr. Victor Horsley removed a Tumour more than a year ago.—Dr. Herringham: A Case of Staggering with Atrophy of the Cerebellum.—Mr. Pearce Gould: A Case of Double Osteotomy for Ankylosis of the Hips.—Dr. Sidney P. Phillips: A Cass of Cross Paralysis.—Mr. Herbert W. Allingham: Case of Dislocation of the Hip—Doubtful Case of Charcot's Disease.

Tuesday, November 1.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

THE PARKES MUSEUM OF HYGIENE.—8 P.M. Dr. Charles Kelly: Sanitary Law—General Enactments, Public Health Act, 1875, Model Bye-Laws.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Specimens:—Mr. Treves: Congenital Cartilaginous Tumour of the Neck.—Mr. Bland Sutton: Spina Bifida Occulta, with Curious Associated Lesions.—Drs. Sainsbury and S. West: Addison's Disease.—Mr. Eve: Relation of Strumous Gland Disease to Tuberculosis, an Experimental Inquiry.—Dr. Wooldridge: On Hæmorrhagic Infarction of the Liver.—Dr. F. C. Turner: Tumour of Spinal Cord.—Mr. Spencer: Compound Comminuted Fracture of Lower Jaw. Card Specimens:—Mr. D'Arcy Power: Submaxillary Gland Removed, with an unusually large Salivary Calculus.—Mr. Spencer: Stump after Chopart's Amputation.

Wednesday, November 2.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Mr. Lowe: A Case of Atresia of the Cervix Uteri with Retention of Menses (Hæmatometra).—Dr. Swayne: Hydrocephalus as a complication of Labour.—Mr. Meredith: A Case of Hæmatometra associated with a Degenerating Fibro-myoma, treated by Supra-vaginal Hysterectomy.

Thursday, November 3.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ABERNETHIAN SOCIETY (St. Bartholomew's Hospital).—Mr. Gow: Cirrhosis of the Liver.

HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Dr. Buzzard: The Significance and Value of Tendon Reflex, Discussed and Demonstrated from an Elementary Point of View.

Friday, November 4.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Pathological specimens will be shown by Mr. Percy Dunn, clinical cases by Dr. Herringham. Dr. Scanes Spicer: On Obstruction of the Nose and its bearing on Ear and Throat Disease and its Treatment.—Dr. Thudichum: On the Varieties of Aconitin and the Dangers of their Medical Use.—Dr. Middleton: On the Advantages of Venesection of the External Jugular Vein in Cardiac Diseases.

THE PARKES MUSEUM OF HYGIENE.—8 P.M. Mr. A. Wynter Blyth: Metropolitan Acts, Bye-Laws of Metropolitan Board of Works.

Saturday, November 5

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

"NOISES IN THE EAR."

IN reply to the communication on Noises in the Ear from a "Subscriber of Twenty Years' standing" which appeared in a recent issue, "F.R.C.S.," while not claiming for himself the position of a specialist in otology, writes that he has little doubt that the Eustachian tubes of the sufferer are not thoroughly pervious. Should this condition be present our correspondent recommends the use of Politzer's bag. Again, should the tympanum be found on examination to be neither thickened nor depressed and the noise is a beating one, like the pulsation of the carotid artery, most probably hydrobromic acid in doses of three grains will relieve it, or hydrobromic acid combined with three-grain doses of F. arnica montana.

A Doctor of Medicine is thanked. We do not, however, think that any advantage would result from publishing at the present time the replies of our correspondent to the series of questions referred to him. The matter seems for the nonce to have passed the acute stage, but interest in it may not improbably revive in the near future.

One Interested in the Case is referred to a letter on the subject inserted in THE LANCET of Oct. 1st, page 682.

Enquirens should consult a solicitor to whom the receipt should be shown.

A "GOOD LIFE" FOR INSURANCE.

To the Editors of THE LANCET.

SIRS,—The following, which is a copy of a private friend's report to an assurance company before a medical examination was instituted, may interest some of your readers, as showing the kind of evidence available before the services of skilled examiners were called into requisition.

"I have your letter of to-day desiring such information as I can give you respecting the 'constitution and general manner of living' of my friend, Mr. A. B——, of —— street. In reply, I beg to say that I consider his constitution a very strong one. He is a good feeder, and takes his bottle regularly, and on occasion can carry off a couple very handsomely. On the whole I think him a very good life for the office to insure."

The proposer was forty-six years of age; the date of the proposal, 1806. In spite of his regular bottle he attained the age of seventy-four, when he died of dropsy. In these days assurance offices look very charily on men who take considerably less than the liberal allowance of alcohol indicated above. That the proposer was a "good feeder" may account in some measure for the age he attained, notwithstanding the quantity of alcohol he consumed. There can be no doubt, I think, that if a man's digestion is sufficiently good to enable him to enjoy his food he can take an amount of alcohol which would soon terminate the existence of a less robust individual. I am, Sirs, your obedient servant,

Wimpole-street, W., Oct. 21st, 1887. F. DE HAVILLAND HALL.

ABUSE OF HOSPITALS BY THE WELL-TO-DO.

Mr. S. Constable.—Our correspondent's remedy is terribly radical, and withal slightly impracticable, not to say unjust. The public must be consulted as to its consultants, and it is not probable that they would agree to decline the services of leading physicians and surgeons to suit a doubtful scheme for the reform of hospital abuse. They might change their ordinary adviser for one who was more reasonable. Besides, is it the duty of hospital physicians and surgeons to investigate the social condition of patients? This would be an intolerable addition to the exhausting duties of the out-patient department. Were a given physician or surgeon to admit a case into hospital which can well afford a reasonable fee to a less famous but equally competent practitioner, we think there would be just ground for public complaint. We agree that the out-patient departments need reform. A scheme for co-operation with provident dispensaries will shortly be presented, and the public and the profession will expect it to be very seriously considered. But let us put the saddle on the right horse, and not turn our young consultants into detectives of the Charity Organisation Society.

S. S.—The second edition of Huth's "Marriage of Near Kin," just published by Longmans, will give the information.

"THE NAVAL MEDICAL SERVICE."

To the Editors of THE LANCET.

SIRS,—I read the letters in your issue of Oct. 8th and 15th by "Surgeon R.N." and "Another Naval Surgeon," anent the desirability of passing through a course of hospital practice for naval medical officers, after foreign service in small ships, where practical knowledge in professional work becomes decidedly rusty, and am glad to see the same ambitious desire exists now as in my junior days in the service amongst many, if not all, young surgeons, regarding a wish to keep up to the times in a profession where we are always students. The idea is an excellent one, if it could only be carried out; but alas! there is but a small chance for the surgeon, and none as a staff-surgeon, with the growing discontent that now prevails. A roster for foreign and home service should exist. Such a thing is possible for the surgeons' list, but impossible for the next grade in its at present attenuated form. At present, officers returning home invalided or paying off are disposed of in the most haphazard manner. An officer of over thirteen years' service, recently invalided from the Mediterranean station, after a prostrating illness of five months from that most intractable of all fevers, tropical typhoid, within six weeks of his last attack was sent down to Sheerness to join a vessel about to proceed direct to Zanzibar. His health, however, soon became impaired in that fen district, and through special appeal to the Admiralty an order for survey was made out, and he was not allowed to go, to be probably returned amongst the "deeply lamented" of those serving their country on the east coast of Africa. But who was sent in the place of that person? A staff-surgeon who had only been home a few weeks from foreign service on the China station, three hot seasons of which were spent in Hong-Kong. Another staff-surgeon was sent abroad; but a few weeks after return from a commission abroad he unluckily contracted fever whilst on passage to his ship, and died. The staff-surgeon's list was then exhausted, and finally a surgeon obtained the billet. "A Naval Surgeon" can now see that it is out of the question for a naval staff-surgeon to obtain sufficient time for a practical hospital course whilst the list is in such a skeleton condition. Now, as regards the degeneration into mere machines of routine. It was but a short time ago that a young surgeon, fresh from Haslar and full of zeal, doing duty in a harbour ship, went to one of our large naval hospitals to follow up an interesting case sent there from his ship. To his surprise he was looked upon as an intruder, a nuisance, and denied a perusal of the bed-ticket on which was noted the interesting information he sought. With such treatment, and the inevitable disgust of the service that grows on one as we near our twenty years, is it surprising that that zeal which is so characteristic of our young naval surgeon gradually dies out as time goes on, and that, unless he is lucky enough to get more than one home-going appointment, however desirous he may be of keeping up practical work, he cannot avoid becoming a mere machine of routine, disgusted, disheartened, living by, but not in, his profession.

I am, Sirs, yours faithfully,

Oct. 18th, 1887. A NAVAL STAFF-SURGEON.

PRESERVING MILK BY OXYGEN.

A METHOD of preserving milk by injecting oxygen into it in a closed vessel has been proposed and patented by M. Brin.

Mr. T. W. J. Allen.—The specimens are undoubtedly maggots—i.e., larvæ of some insect the ova of which may have been swallowed by the patient. In reference to this subject the late Dr. Cobbold writes:—"In actual practice it is not uncommon to find the larvæ of various species of moths (*Noctuæ*) either in the night-stool or chamber utensil, these for the most part being accidentally introduced. In like manner the maggots of various butterflies and other insects are often passed, having been previously swallowed along with food" (Quain's Dict. of Med., art. Œstrus). Dr. Cobbold says that ordinary purgatives, clysters, and vermifuges, especially turpentine, will usually dislodge them.

Dr. A. W. Stirling.—The paper is marked for insertion.

Digitized by Google

"NEW URETHRAL INSTRUMENTS."

WITH reference to the article by Mr. Distin-Maddick which under this heading appeared in our last issue, Dr. D. Campbell Black writes stating that the instrument described by Mr. Distin-Maddick exactly corresponds to the compound catheter of the late Dr. Andrew Buchanan of Glasgow, with the use of which Dr. Black became familiar in the wards of the Glasgow Royal Infirmary considerably more than twenty years ago. Our correspondent strongly deprecates the "inventive propensity" which is now becoming so general, and which he opines serves no good purpose.

Dr. R. Neals.—A visit to the premises indicated would, we fancy, show that the card in question is in the nature of a trade advertisement.

"THE VALUE OF SHORTHAND TO THE STUDENT AND TO THE PRACTITIONER OF MEDICINE."

To the Editors of THE LANCET.

SIRS,—Students of all classes owe a debt of gratitude to Dr. Gowers for his timely and useful suggestions upon the "Value of Shorthand" contained in your issue of the 8th inst. These having been read before the International Shorthand Congress, and copied from your columns into local papers, have been diffused far beyond the ranks of our own profession. There are, however, many busy practitioners, and even students well advanced in their curriculum, who cannot afford the "hour a day for three months," which Dr. Gowers says "will, in most cases, suffice to give the needful dexterity." It may be of some use to those so situated to learn that a modified system of stenography may be acquired with a little practice, which, though it cannot compare with the complete shorthand writing of the present day, is, nevertheless, of the utmost value for most of the purposes to which Dr. Gowers refers. The one I used during my student's days, and which I have found invaluable for daily use ever since, is based upon a system first shown to me by the late Mr. Samuel Smith—then senior surgeon to the Leeds Infirmary,—and which he had utilised for note-taking during his studentship. His method was simply that o omitting vowels and writing only consonants, except in the case of some words beginning with a vowel, where it is often more intelligible to insert it. This plan I combine with a series of shorthand signs for consonants, used by my father before me, which, with the addition of dots for vowels, are useful for short words like of, to, which, has, their, with, &c., and also for terminal syllables like ed, tion, ing, ment, &c. Although, by adopting these means, I cannot quite write at the rate of 100 words per minute, or with anything like the rapidity attained by Pitman's phonography, the writing is at least much more rapid than longhand, and can be acquired with comparatively little practice. It is not equal to a *verbatim* report of a speech or a lecture, but the student can with facility take down in the words of the lecturer sufficient to record the main lines of his subject, and is also able to fill in considerable detail; the advantage being that he preserves for future use simply what is written at the time of the lecture, no transcription from shorthand into longhand being necessary. I possess volumes of notes of a large number of lectures written in this way, to which I frequently refer. The notes merely require to be afterwards "dressed" over and finished off where gaps may have been left, so that the listener might not lose what he could not quite keep up with. And here the first difficulty, I believe, of all shorthand presents itself—viz., that it is easier to acquire the power to write than afterwards to read what has been written. Practice will, however, in time get over this.

Another advantage of my system is that anyone may learn to read what is written if provided with the key to it, without knowing anything of pure shorthand. To the practitioner it is invaluable for the many and varied purposes of memoranda and "preliminary composition" to which Dr. Gowers refers—for secretarial notes, for taking down clinical data at the bedside, or in the consulting-room, for reports of cases in the hospital or in a court of law, for entering abstracts and references in a common-place book, in fact, for innumerable purposes in the clerical work of daily life. I make use of the system freely in the notes from which I lecture, and all abstracts from the writings of others are invariably copied in this form, hence an immense saving in time in anything required for my own use only.

I am, Sirs, faithfully yours,

Leeds, Oct. 17th, 1887. CHARLES J. WRIGHT.

LEICESTER AND VACCINATION.

To the Editors of THE LANCET.

SIRS,—Either through a clerical or typographical error, near the close of my letter published in THE LANCET of Oct. 15th, the word "vaccinated" instead of *revaccinated* occurs in the following sentence:—"We have, therefore, in all ten persons who were in office at the time the special report was made, *four of whom had never been vaccinated.*" As in the preceding sentences I had just stated that these four persons *were vaccinated*, it is obvious to a fair and careful reader that the word should have been *revaccinated*. The elderly clerk referred to passed all through the epidemic of 1872 in close contact with a large number of small-pox patients without contracting the disease.

The above points dispose of all in Dr. Tomkins' letter which does not corroborate what I had already affirmed. Dr. Tomkins' recent appointment to the office he holds probably accounts for some of the discrepancies which have arisen. I am, Sirs, yours truly,

Leicester, Oct. 26th, 1887. J. T. BIGGS.

YELLOW COLOURING MATTERS.

DR. WEYL of Berlin, who has been examining the various yellow colouring matters used for macaroni, butter, liqueurs, &c., reports that dinitrocresol, which is sold as saffron yellow, is highly poisonous, four grains proving fatal to rabbits and guinea-pigs in a few minutes. The so-called "Martin's yellow" and "butter yellow" are quite harmless.

G. L. (Birmingham).—Works on the mission of the medical man are common in French and Italian literature. Probably there is no better picture of what a wise practitioner can do for a simple, confiding peasantry than that drawn (undesignedly) in M. E. Littré's autobiographical sketches. The latest contribution to the subject is the "Bozzetti Patologici: Saggi di Medicina Popolare" of Dr. Nestore Mattioli, in which the author shows how much the physician, particularly in country districts, can achieve for the inhabitants in the way of practical hints as to diet, housing, recreation, &c. The removal of prejudices, many of them superstitious, was Dr. Mattioli's chief difficulty; but the demonstration he was able to give of their fallacy (seconded by the treatment adopted in the little local hospital) had its reward in encouragement to perseverance. Ronciglione, an interesting Etruscan village in the States of the Church, was the scene of his labours.

WINDOW CLEANING.

To the Editors of THE LANCET.

SIRS,—I notice in your issue of the 15th inst. an annotation dealing with window cleaning accidents. I believe that there is still in existence an unrepealed old Police Act which prohibits windows being cleaned from the outside, and that refusal on the part of a servant would not disentitle her from claiming her wages. Could any of your readers favour me with further particulars of this Act? There are several patents in existence for reversible windows, and notably that of Mr. Robert Adams' of 17, Blackman-street, S.E., which appears to be perfect.

I am, Sirs, yours obediently,

Lansdowne-road, W., Oct. 25th, 1887. ARTHUR DICK, F.R.G.S.

To the Editors of THE LANCET.

SIRS,—Having seen in a local newspaper an article taken from a recent issue of THE LANCET commenting on the above subject, I wish to draw your attention to an invention in windows and their fastenings invented by a cabinet-maker of this place, by which the evils mentioned by you can all be avoided. It is so constructed that all pulleys, weights, and cords are dispensed with, and it can be fitted to almost any ordinary kind, size, and shape of window. Opening from the inside, all accidents from outside cleaning are impossible. Especially for hospitals and the sick-room it is an admirable window, ventilation being regulated by means of a screw, which is so adjusted that air is easily admitted without draught and in an upward direction, whilst all shaking and jarring, so distressing to invalids, is avoided. Having seen it in actual use, I am convinced it is the window of the future, and from the simplicity and economy of its construction, I feel sure it will commend itself to those interested in the erection of hospitals and other public buildings, as well as to those who are familiar with the defects of their own badly-fitting, draughty, and dangerous windows. I enclose a circular which will more lucidly explain the mechanical detail of the contrivance.

I am, Sirs, yours truly,

GERALD COLEMAN,

Medical Officer of Health, Hemsworth Sanitary Authority.

Hemsworth, Pontefract, Oct. 24th, 1887.

*** The inventor referred to by Mr. Coleman is Mr. Richard Mason of Hemsworth. We have also received a circular descriptive of, and had an opportunity of personally examining, the Patent Safety Sash produced by Messrs. Lloyd and Co., 37, Great James-street, Bedford-row, W.C. This appliance seems to perfectly achieve the object aimed at, and is comparatively inexpensive, the cost of adaptation to existing windows being of course slightly higher.—ED. L.

HOME FOR INEBRIATES OF LIMITED MEANS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me of a Home licensed under the Habitual Drunkards Act, 1879, where the wife of a working man could be kept for a time for a moderate sum per week? The husband of course is unable to pay anything like the charges for residence in the homes advertised weekly in THE LANCET.

I am, Sirs, faithfully yours,

Huddersfield, Oct. 26th, 1887. DAVID WILSON, M.D.

THE COMMUNICATION OF RABIES.

To the Editors of THE LANCET.

SIRS,—On page 841 of your last issue is a paragraph headed "A Precursor of Pasteur," and the basis of it is that rabies can only be communicated by carnivora, and not by herbivora, when affected by it. As this statement may be accepted by many of the uninitiated, may I point out that it can readily be communicated by herbivora, as has been demonstrated in the late outbreak among the deer in Richmond-park.

I am, Sirs, yours faithfully,

London, Oct. 22nd, 1887. JAMES LAMBERT, F.R.C.V.S.

ALCOHOLISM AND VICE IN PERSIA.

DR. JABLONOWSKI, who has contributed some sanitary notes on Persia to a Polish medical journal, states that the use of alcoholic liquors (brandy and wine) has of late become greatly extended amongst the upper classes, alcoholism in various forms being now a very frequent affection, as those persons who have taken to drink scarcely pass a single day without becoming intoxicated. This, too, is attended with still greater evils, as during their orgies they give themselves up to vice in revolting forms.

M.B.—We fear our correspondent has no legal claim against the police-court officials. If he was summoned by the relieving officer, who is the representative of the guardians of the poor, he must seek for remuneration for his services from him. It is doubtful though whether he could recover professional fees, as an objection might be raised on the ground that his subpœna was issued in order that he might testify to a simple matter of fact—viz., that he had certified as to the mental condition of a pauper.

Messrs. Engelhard and Co. (Chicago).—We cannot exchange.

PARALYSIS OF THE ABDUCTORS OF THE VOCAL CORDS.

To the Editors of THE LANCET.

SIRS,—Dr. Gordon Holmes has omitted from his list a case of mine published in the *Birmingham Medical Review* for December, 1885, of bilateral paralysis of the abductors in tabes. It is one of the few in which a post-mortem examination is given. It is of interest to mention a case of unilateral paralysis due to goitre in a lady. She has had several attacks, but they have all been of a temporary nature. When the paralysis is present she has nocturnal paroxysms of dyspnœa like croup. The immediate exciting cause appears to be cold, though the pressure of the tumour on the recurrent laryngeal is doubtless the predisposing and persistent condition.—Yours faithfully,

ROBERT SAUNDBY, M.D.Edin., F.R.C.P.Lond.

Birmingham, Oct. 22nd, 1887.

"LARYNGISMUS STRIDULUS."

To the Editors of THE LANCET.

SIRS,—I am obliged to Dr. W. H. Barlow for his letter drawing attention to my mistake. What I intended, and ought, to have said was that the value of cod-liver oil was not sufficiently emphasised. "Può essere dato" (may be given) should read, "dovrebbe essere dato" (ought to be given). Dr. Barlow will find one or two drops of tincture of opium given with the oil very useful in cases where the oil alone causes diarrhœa, as it not infrequently does, even in small doses.

I am, Sirs, yours faithfully,

Oct. 24th, 1887. YOUR REVIEWER.

LINIMENT FOR CLUB USE.

To the Editors of THE LANCET.

SIRS,—Will some correspondent kindly give the formula for really stable and cheap liniment for club use? The various forms of lin. alba are not always free from lumpiness in frosty weather.

I am, Sirs, yours faithfully,

Oct. 25th, 1887. CLUB.

Inaugural Address

ON

WORK DONE IN SURGERY BY ITS PROFESSORS IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

Delivered at the Opening of the School of Surgery, Royal College of Surgeons, Session 1887–88,

BY SIR WILLIAM STOKES, M.D., CH.M., F.R.C.S.,

PROFESSOR OF SURGERY AND EX-PRESIDENT, ROYAL COLLEGE OF SURGEONS, SENIOR SURGEON TO THE RICHMOND SURGICAL HOSPITAL, FORMERLY PRESIDENT OF THE PATHOLOGICAL SOCIETY OF IRELAND, ETC.

MR. PRESIDENT AND GENTLEMEN,—It is not of my seeking that I occupy the position of lecturer to-day; it is by the will of my colleagues that I am here; and although I doubt the wisdom of their choice, I cannot refrain from an acknowledgment of so signal a mark of their confidence. It seems to me there is a peculiar responsibility and importance attached to the opening of this session, as we are, so to say, entering upon a new dispensation. "The old order changeth, yielding place to new." We are now, in truth, ringing out the old system and ringing in the new; and this process is fraught with consequences of the utmost gravity and importance, not alone to the student, but also to this College, the profession, and the public at large. Since the last inaugural address was delivered here a union has taken place between this College and the other medical corporations of Ireland. Hence the student in medicine has now to look forward not alone to sessional examinations, but also to a final one, conducted not as heretofore by one, but by two of the medical authorities. From this union of our College with the other corporations I anticipate the best results. The want of it has too long been a source of weakness to our profession, kindling feelings of mutual jealousy and distrust, and therefore keeping us divided, powerless, and weak; and although in the negotiations between the licensing bodies many feathers have been, and still are, ruffled, and the union not as comprehensive as I trust I may live to see it, still a good beginning has been made, and I look forward with confidence to witnessing a happy reciprocity and overlapping of our work, and an approach made to that end desired by all—unity in the science of medicine.

Although much hostile criticism has been devoted to the new curriculum and the sessional system of examinations—one which with certain students will always remain unpopular,—still, to those who take a far-seeing view of the situation, the merits of both must soon become apparent. As regards the former, I would allude to the accentuation of the necessity for a much larger amount than was hitherto required of what may be called extra-professional education—a wise provision in the interests of the social advancement of our profession,—inasmuch as this is influenced and promoted, as has been well said, not so much by its prominent heroes as by the impulse given by the culture and mental powers of the masses in it.

The sessional system of examination authoritatively emphasises the necessity for abandoning for ever the method that formerly was too prevalent, of leaving till the last few months of pupilage all honest and earnest effort to master a sufficiency of anatomical and surgical details to satisfy the examiners. That system was as discreditable as it was pernicious to all concerned—students, teachers, and examiners alike; and it is amazing how it was tolerated by the authorities for so long a time. You are to be congratulated, instead of being sympathised with, at the extinction of such a system, and upon joining the ranks of our profession when the student in medicine occupies a far different and far higher position in public estimation than formerly was the case, and when the being, so ably satirised by Albert Smith and Dickens, who, fashionably dressed, vaguely "walked the hospitals" in the morning, and, subsequently, in the afternoon was an ardent "fire worshipper" in the dissecting rooms, is no longer to be found. Such a creature exists now, I am happy to say, only in the limbo of a discreditable tradition, and is as completely extinct as the Dodo.

If there are any among you who regret that their lot has fallen on these days, when frequent examination and constant toil, from the beginning to the end of your student career, seem to be essential to success, I would ask you to bear in mind and take comfort in the reflection that your present lot is not exceptional, that similar and frequent testings are found necessary for all who study other arts and other sciences with any hope of success. What would be thought of a student in engineering, or sculpture, or painting, or any other art or science whose proficiency was never tested, and who postponed all real work at those subjects until a few months before he demanded and expected public recognition in them?

It may be said that such examinations during the different stages of your progress are like the tests and exercises of your physical powers in your training for athletic exercises. All of you are, I trust, more or less proficient in these, and know something of the frequent measuring of your powers for your Olympian contests. If such contests are found to be essential to success, is it not important that even greater precautions should be taken to ensure success in the long professional contest in which most of your lifetime will be spent? and especially is it not more so in the profession you have chosen, in which the competitors are so many, and the honours and prizes comparatively few?

In your professional work, however, both as pupils and subsequently as practitioners, you should endeavour not to be influenced solely by the principle of working only for an immediate tangible result, of which Schiller spoke so contemptuously, as actuating what he termed the *Brotgelehrte*, or bread scholars. But first I must guard against the possible assumption that, in referring to this passage of the great writer, I hold that there is anything unworthy in looking forward to the acquisition of professional knowledge as a means of livelihood. Such a doctrine I hold to be preposterous, and only to be classed with poets' dreams; but I would impress upon you that the *Brotgelehrte* principle should not be the sole or even the main motive force in your efforts, as, I am sorry to say, it is with so many. Rest assured that work done for its own sake, irrespectively as to whether the results be tangible and practically useful or not, is, as a rule, the product of minds intellectually as well as morally far superior and capable of greater acquirements than those of persons whose objects are mainly personal advancement and the accumulation of wealth. The nobler class illuminate the path of science with lamps which ever burn with inherent fire; the others are like the lesser stars, which owe their brightness to reflected light.

In this school, as I know by pleasurable experience, the students have been, as a rule, ever animated by the three great motive forces which promote all good things—earnestness, enthusiasm, and honesty in work; and I feel confident that in the coming session you who constitute the class of the school of this College—a school hallowed by so many worthy memories and noble traditions—will not be behind your predecessors in proving yourselves capable of honest effort; determined to be true to yourselves, true to those nearest and dearest to you, who, perhaps, in some instances at great personal sacrifice to themselves, have sent you here to acquire your professional training. One of your main ambitions should be not to be haunted in after life by the disturbing and paralysing spectres of lost opportunities; and so at once grasp the golden grains of knowledge set before you, and, above all, keep records of what you see and what you hear both in hospital and school. Let your motto be—"Nulla dies sine linea." It was said by a distinguished author—Anthony Trollope—that "students should let their work be to them as is his common work to the common labourer. No gigantic efforts will then be necessary. He need tie no wet towels round his brow, nor sit for thirty hours at his desk, as men have sat, or said they have sat." Remember that constancy in labour will conquer all difficulties—"Gutta cavat lapidem non vi sed sæpe cadendo." At once therefore commence to make the most of the precious but irrevocable years of student life—years as fleeting as the clouds in a summer sky, which once gone never can return;

and ever bear in mind the truth of the old adage: "By the street of By-and-bye one arrives at the street of—Never."

"Gebraucht der Zeit, sie geht so schnell von hinnen,
Doch Ordnung lehrt euch Zeit gewinnen."—*Goethe.*

It has been noted as a peculiarity of our countrymen that they have a tendency to keep feeding their minds on the memories of bygone days, and to devote themselves to the contemplation of the achievements of their predecessors. There may be some truth in the charge; but, though the too frequent indulgence in the practice is certainly to be deprecated, it is at times not only fitting but right to recall the work done likely to endure, and the progress made by those who have preceded us. On the present occasion, however, I shall confine myself to making a retrospect, necessarily a swift and fleeting one, of the chief surgical work accomplished by many of my predecessors in the surgical chair of this College, in which survey I have to acknowledge with gratitude the assistance I have derived from the comprehensive History of the College by my friend and colleague, Sir Charles Cameron. An apology is hardly necessary for taking this course, as the labours achieved by these masters of our art have in so many instances acted as starting points for investigation, and resulted in new departures in our knowledge of surgical pathology, and consequent improvements in surgical therapeutics. While time and subsequent research have led to the rejection of certain views promulgated here, still it must be admitted that the great bulk of the work of our surgical predecessors has been accepted and their doctrines verified; but, irrespective of their acceptance or their rejection, one great good resulted, one precious legacy they bequeathed to us, which was the great and salutary impulse to effort that actuated them—that impulse which we call progress. The history of their work is, in truth, full of inspiring memories and pregnant with far-reaching hopes; and no one who studies it can fail to become sensible of the fact of the great responsibility which is attached to those who follow even "*longo intervallo*" the steps of many of the great surgeons who made this school the arena for their labours.

William Dease, whose statue so fitly adorns the hall of this College, was the first Professor of Surgery here, was an original member of the Dublin Society of Surgeons, one of the most energetic founders of this College, and a distinguished member of the surgical staff of the Meath Hospital and County Dublin Infirmary. He was a wise and philosophic surgeon, whose works, even when read by the light of modern investigation, remain, and are rightly considered, classical. They remain so, not only because they were the works of a conscientious and accurate observer, but also because they were written from, and not for, practice. His works "On Obstetrics," "On the Radical Cure of Hydrocele," "On the Treatment of Venereal Disease," and, lastly, his great work "On Injuries of the Head," would have been more than sufficient to render his name famous. He first recognised and taught the great fact in reference to the late appearance of evidence of cerebral inflammation, and its sequelæ after injuries of the head. In illustration of this pathological fact, noted by Dease, I may briefly recall two notable instances in my own practice in the Richmond Hospital, in one of which cerebral trouble did not become apparent until eight weeks after the receipt of the injury, which was a blow from the handle of a reaping-hook. The patient had gone to the north of England for employment at harvest operations, and sustained the injury during a dispute with some fellow-labourers, who emphasised their arguments by blows. No immediate bad consequences supervened, and for seven weeks after he was able to continue his work. He then returned to Ireland, and shortly after his arrival, and eight weeks after the injury, symptoms of cerebral pressure occurred. In the second case the injury was the blow of a hammer, which was inflicted six weeks before any serious mischief was apprehended. Oddly enough, the injury in both cases was inflicted just over the left temple, and as regards the symptoms also there was the closest analogy. There was evidently brain pressure in both cases, indicated by slowness of pulse, complete motor paralysis, retention of urine, myosis, and complete insensibility, but in both cases an absence of stertorous breathing. I trephined in both instances over the seat of the injury. In the first case the cranial opening was, as in a third case in which I performed the operation of trephining for intracranial hæmorrhage, within a hair's breadth of the source of pressure. Had I in this case the confidence in dealing with it that antiseptic surgery has now given us, I would have made other openings, and doubtless have relieved, and probably have saved, the patient's life. In the second case, in which a cerebral abscess, the result of injury, was diagnosed, and which occurred in my practice in the Richmond Hospital last August, I was more fortunate. The patient, a young man aged twenty-four, at the time of the operation was speechless and unconscious, the paralysis both of motion and sensation complete, together with the other evidences of pressure above noted. He had, in addition, frequent convulsive seizures, confined altogether to the right side, after each of which the insensibility appeared to become, if possible, more profound than before. The patient was clearly *in extremis*. In this apparently hopeless case, assisted by you, Mr. President, and my colleague Mr. Thomson, I trephined over the seat of the injury. On raising the flap, I found that there was a fracture of the outer table of the bone—a small portion of which, about the size of a threepenny piece, was detached. There did not seem to be any depressed fracture. I then applied the trephine and raised the bone, and on finding no evidence of effusion of any kind between the bone and dura mater experienced a veritable pang of disappointment. I then pierced the dura mater with the needle of a hypodermic syringe, and on drawing up the piston again experienced disappointment at getting a negative result. I then passed the needle deeper, but with a like result. I was then about to withdraw it and abandon my efforts to relieve the patient, when I determined, having gone so far, and strengthened by the full concurrence of my colleagues, to make one final attempt to pass the needle down as far as ever it could go. I did so, and my satisfaction was, I need hardly say, intense when, on drawing up the piston, a few drops of pus were apparent in the glass receiver. I then freely opened the dura mater, and, using the needle as my guide, sank the blade of a narrow-bladed bistoury down to the abscess, the contents of which welled up to the surface. I completed the evacuation of the abscess by passing into the cavity a piece of indiarubber tubing, and, attaching one end of it to the nozzle of a glass syringe, succeeded in drawing or pumping up the contents of the abscess. About an ounce and a half of dark grumous pus was in this way obtained. I then washed out the cavity with a warm 1 per cent. solution of carbolic acid, and then, leaving a drainage tube in, replaced the flap and dressed it with sal alembroth gauze and iodoform wool. I need not give, on the present occasion, any further details, but may state that before the patient left the operating theatre his power of speech returned; in less than three hours there was a marked improvement in all the paralytic symptoms, and ultimately the recovery was complete.

The case is remarkable and deserving of record, not only in consequence of the late appearance of the results of inflammatory mischief, but also from the fact of the satisfactory result of the operation, the case being, as far as I am aware, the second in which the operation of evacuating a deep-seated traumatic cerebral abscess was performed; the first in which it was done having been in Dupuytren's celebrated case—probably the most splendid operative effort ever achieved by that illustrious surgeon. The other cases of cerebral abscess from traumatism for which trephining has been performed, have been, as far as I can ascertain, without exception peripheral. The cases above alluded to I mentioned from their being so signally illustrative of Dease's doctrine as to the late appearance in many cases of inflammatory cerebral mischief after cranial traumatisms.

Following Dease, whose death, attended with such tragical circumstances, was a blow to the cause of scientific surgery in Ireland, came one of the most remarkable teachers of surgery that probably ever existed here or elsewhere. I allude to Abraham Colles, whose works hardly need to be enumerated, as they are doubtless familiar to most or perhaps all of you. If asked on what I thought Colles' fame would ultimately rest, I would say, first, the great and salutary revolution which he effected in the treatment of syphilis, and which resulted in the abandonment of the reckless and indiscriminate use of mercury, and the advocacy of the principles that should guide us in the administration of the drug—principles now accepted by modern therapeutists of the very highest authority. In this respect Colles proved himself to be a true pioneer, and clearly in advance of his time. Secondly, the graphic and accurate description of fracture of the lower end of the radius—the one

Digitized by Google

which fitly bears his name,—his account of it being all the more remarkable from the fact of his never having had an opportunity of dissecting an example of the injury. And lastly, the enunciation of what Mr. J. Hutchinson has designated "Colles' law"—that, namely, in reference to the immunity which mothers of congenitally syphilitic infants have against infection from their offspring, an immunity not enjoyed by the nurses previously unaffected. As regards his powers as a teacher, no better proof could be given of the high estimate that was formed of them than the resolution which was passed by the College on his retirement from the chair of Surgery. It ran thus: "It was the unanimous feeling of the College that the exemplary and efficient manner in which he has filled the chair of the Theory and Practice of Surgery for thirty-two years had been the principal cause of the success and consequent high character of the School of Surgery in this country." Colles was, as has been well said, "an example to all of what may be achieved by accurate observations and truthful record." With the former, many of them original, his works are replete. Some have undoubtedly been appropriated by others, but, in truth, it may be said of him in regard to his works what was observed of a celebrated French philosopher and jurist, that even "when pillaged by all, he is still rich."

Next in order came a no less eminent teacher, one who occupied a foremost place among the *dii majores* of the surgical profession. I allude to Prof. W. L. Porter, the father of my esteemed friend, colleague, and former teacher, Sir George Porter. Prof. Porter's researches, carried on in the Meath Hospital, on the surgical staff of which he was for over forty years, on aneurysm, on syphilis, and on the diseases of the larynx and trachea, on which latter subject he published a work which must always be reckoned among the surgical classics, justly acquired for him a world-wide reputation; and although to one important doctrine of his, in reference to the inutility of the operation of tracheotomy in croup or diphtheria, exception may, I think, be taken—a doctrine which, having regard to the time he lived in, he doubtless had good grounds for holding and maintaining,—still I feel confident that had he lived and worked during the present era, in which we have the advantage of many additional surgical improvements and appliances that did not formerly exist, he would have modified those views and become satisfied that the operation in the great majority of such cases not only gives great and immediate temporary relief, but that in a considerable proportion of them it is distinctly a means of saving life. This statement is based not alone on the results of statistical research, which show that there have been 26½ per cent. of recoveries in these cases after the operation, but also on the experience I and my colleagues have had in the Richmond Hospital. We cannot, it is true, boast of any lengthened list of recoveries after the operation in these cases, but still there have been some, and doubtless there would have been others if the cases had been available for operation at an earlier date. But in all the temporary relief obtained was most remarkable. As a lecturer Professor Porter was unequalled. His earnest eloquence enthralled his pupils, and his frank and ready appreciation of what he believed to be true was only equalled by his fearless denunciation of, and scathing sarcasm in dealing with, what he believed to be untrustworthy and false. He was, in truth, no "dry-as-dust" a teacher. His hearers were supplied from no ancient eroded cistern or stagnant pool, for he had the power, possessed by so few, of being able to strike the rock from which came the living water.

Associated with Professor Porter was Mr. C. Todd, the father of the eminent physician, Robert Bentley Todd of King's College Hospital, London. Mr. Todd, who was also secretary and librarian to the College, was not a prolific author, but a conscientious and successful teacher, and his papers in the Dublin Hospital Reports—that mine of scientific wealth—are characterised by an essentially practical spirit. With his name must be always associated the introduction in the Richmond Hospital of the pressure treatment of aneurysm, that known as the "Dublin treatment." It was in a case of Mr. Todd's that the treatment first proved successful.

As regards the efficiency of this method of treatment, however, I cannot but think that surgical opinion is destined at no distant period to undergo considerable change, owing doubtless to the diminished risk now attending arterial deligation. In other words, I regard the treatment we have so long justly taken pride in as having originated here as being, to a great extent, deposed from the lofty pedestal on which it has for so long a period fitly rested. In a large proportion of cases I believe it to be not only unreliable as a means of cure, but likely, if persisted in for any length of time, to militate against recovery being obtained when other and surer means of cure are subsequently adopted. In illustration of this I may instance, among others, three examples of aneurysm—one a radial, the second a femoro-popliteal, and the third a popliteal. In all three cases pressure was tried for a lengthened period, and without effect. The failure, in fact, in all was signal.

In the case of the radial aneurysm I subsequently tied the artery—and this, owing doubtless to the too free collateral circulation that was established, was also unattended with success, and eventually I had to excise the aneurysmal tumour, performing the old operation of Antyllus.

The second case was a femoro-popliteal aneurysm, which was under my care so far back as Aug. 17th, 1870. In this case I commenced making pressure on the femoral artery, using alternately Read's and Carte's artery compressors—the former on the groin, and the latter at the middle of the thigh. After four days and nights' continuous pressure no difference was observed in either the size or consistence of the tumour. Digital pressure was also applied for two days, but with a negative result. I then exposed the femoral and placed a temporary ligature upon it, using Porter's clamp. This was removed after fifty hours, but without any satisfactory result, and eventually, the aneurysm having become diffused, I had to amputate the limb. I feel satisfied that, had a ligature been applied to the artery in the first instance, a different result could have been recorded.

In the last case I would allude to—that, namely, of popliteal aneurysm, one which has recently been under my care in the Richmond Hospital—pressure had been intermittently employed for a long period (viz., over three months), and I have no reason for supposing that it was not done with the highest degree of efficiency; but, as in the other cases, the result was unsatisfactory. The case then came under my care, and though urged by some of my surgical friends to continue the pressure treatment, I preferred, having regard especially to the latter having got, as I believe, an ample trial, to deligate the artery. There was immediate and firm union of the wound; no evidence whatever of pus production; but shortly after the operation a very distinct pulsation returned in the aneurysm, which continued for several weeks—so long, in fact, that I began to fear that the operation was not going, as far as the cure of the aneurysm was concerned, to be a success. Eventually, however, the result was eminently satisfactory. In this case, therefore, the pressure treatment not only failed to cure the aneurysm, but owing, as I believe, to the too free collateral circulation that was established as a consequence of the prolonged pressure, the recovery after the operation was distinctly retarded.

The lesson, therefore, to be learned from these as well as other cases that might be adduced, is that, unless some hindrance or contra-indication exist, the surgeon who feels himself competent to perform efficiently arterial deligation and able and willing to perform it in a thoroughly antiseptic manner, should prefer it to, at all events, any prolonged treatment of pressure, or to any of the other numerous eccentric devices that have been proposed from time to time by various persons craving for notoriety and a little ephemeral reputation, and who in this way veil their surgical incompetency under a garb of supposed originality.

Succeeding Mr. Todd came Mr. J. Wilmot, who contributed many able surgical papers to the Dublin Hospital Reports and *Dublin Quarterly Journal*. His fame as a surgical author will mainly rest on his work on "Diseases of the Prostate," in which he was deservedly regarded as a high authority.

The last of the occupants of the Surgical Chair of this school I would allude to is my immediate predecessor, Professor Hargrave, who for a long series of years ably maintained its reputation and prestige. Numerous papers on many practical surgical topics bear testimony to his unceasing industry, energy, and powers of accurate observation, and finally his work on "Operative Surgery"—one too little known and appreciated—fitly placed him in the front rank among his surgical contemporaries.

It will thus be seen that in advancing and elucidating many of the greatest and most important branches of surgery, such as, among many others, fractures, aneurysm, syphilis, injuries of the head, diseases of the genito-urinary organs, of the larynx and trachea, and also in the wide, in

Digitized by Google

truth almost illimitable field of operative surgery—subjects which have for so long a time agitated, and are still agitating, the surgical world—the occupants of the chair of Surgery in this school have been original investigators and leaders, whose work has stood the test of time, the most of it being still and likely to continue accepted.

Briefly regarding it, as we only can do on an occasion like the present, work of such rare excellence as has been achieved by our surgical predecessors here cannot but act as a healthy stimulus to further effort, not only on the part of your teachers, but also on your part; for all, teachers and pupils alike, are or should be actuated by the worthy ambition which so largely influenced those who preceded us, which had for one of its chief objects the maintenance of the prestige and reputation of this great and time-honoured College and the Irish School of Surgery. In the present day exceptional difficulties and obstacles doubtless exist in the advancement of our art which did not, at all events to the same extent, hamper the efforts and retard the work of those who went before us. These difficulties still exist, and are likely to continue, until, in more enlightened days, they are swept away with the contempt which they so richly merit. I allude more particularly to the difficulties thrown in the way of the experimental physiologist in these countries, and to the cruel and insensate opposition made to the action of the Contagious Diseases Acts, both striking illustrations of how sentiment may get the better of judgment, and both mischievous products of what has been well termed the *lues philanthropica* — that weak, flabby, boneless, utopian humanitarianism now so prevalent, and that has done so much to sap the judgment, discretion, and good sense of so many men as well as women. You should look upon it as one of your great duties and privileges, in the present as well as in the future, to aid in bringing about that happy era, sure to come sooner or later, when all such opposition and obstacles shall exist only among the traditions of our art, and when, to quote Graves' noble words, "the stream of knowledge, now fed by a thousand new sources, flows along deep and rapid, sweeping away every obstruction, and defying all human opposition." Then the obscuring mists of prejudice and folly will be lifted off the ground and dispersed as by a magician's wand, and the physician and surgeon will not have so often to fold their arms and sorrowfully confess that they can do no more, confess that they stand baffled and powerless in the presence of disease, which perhaps they may have vanquished for a time, but never conquered; then the State will no longer be guilty of thwarting efforts which, if allowed to be made, would, we know, aid signally in stamping out that fell disease which is such a cruel and relentless scourge and curse to humanity, which counts more victims than cholera, small-pox, or yellow fever put together, and which spares neither age nor sex, not even the innocent child unborn.

In your professional life hereafter, if slow to accept new principles and practice, be also slow to reject them. Remember there is nothing so cheap or so nasty as senseless detraction, nothing so vulgar, so stupid and contemptible as an unreasoning scepticism, and that indulgence in either or both has not infrequently brought persons into a position at once melancholy and at the same time ludicrous. I allude more particularly to the hostility that was formerly evinced by "practical" persons to the many instruments of precision now so indispensable to every educated practitioner, and of late years mainly, I regret to say, in the surgical ranks of our profession, to the principles and practice of antisepticism as elaborated by Pasteur and Lister. When we consider how recently we have heard antiseptic practices held up to contempt as little else than a fashionable but essentially ephemeral craze, and its professors and advocates described as persons apparently temporarily afflicted with a form of harmless lunacy, which in time, and with a more extended experience, they may reasonably be expected to recover from, we have a good example of the humiliating position unthinking detractors may eventually find themselves in.

You may be well congratulated at beginning the work of your lives—that which I trust may soon prove to you all a happy toil—at a time in which the advances made and the results obtained have been so great as to justify its being termed the "Golden Age" of surgery, and to prove how rash it was even of so great a surgeon as Boyer, upwards of seventy years ago, to express his conviction and belief that surgery had already attained perfection. In dealing with the present epoch, the historian will doubtless place in boldest relief the revolution that has taken place in the treatment of wounds, one which has been attended with such amazing results, and brought about, not by any chance or inspiration, but by the application of knowledge gained from three of the great sources of scientific wealth—Physiology, Chemistry, and Therapeutics.

As a proof of what we have gained in our power of warding off and disarming what are not inaptly termed "preventable" diseases following wounds, all more or less connected with septic infection, let us briefly glance at some facts connected with comparatively recent wars, for which I am indebted to my friend, Sir William Mac Cormac.[1] In the Crimean war the number of men who lost their lives in the French army was 95,615, of which only 10,240 perished at the hands of the enemy, the remainder succumbing to diseases resulting directly from their wounds. In the American war 95,000 men died from wounds, while 184,000, nearly double the number, perished from septic affections consequent on them. A remarkable change for the better was observed in the Franco-German war. In this campaign 28,282 died of their wounds, while only 12,253 died of preventable disease. But the greatest result of all yet obtained was in the Egyptian campaign of 1882, in which not a single instance of death from pyæmia, septicæmia, erysipelas, or hospital gangrene is recorded.

In fulfilling the task you have laid out for yourselves to accomplish, I trust you will be not merely steady workers, but earnest enthusiasts. I believe that in the study and scientific pursuit of our profession the highest exercises of the mind are required, and the best charities of the heart are elicited. To ensure an honourable success here—by which I mean not so much the acquisition of State honours or wealth, as the sympathy and good opinion of your contemporaries—bind yourselves by a true and exalted line of conduct; be strong, courageous, and stern in resisting all temptations to evil-doing; cherish always the worthy aspiration that your energy in all right and honourable action may not fail, and that you may not, in consequence, fall into that hopeless quagmire of mental stagnation into which so many sink, and from which so few have power to emerge; and, above all, remember that those talents with which you have been entrusted—to some more and to others less—should not be wrongly buried in the ground, but returned with interest to Him to whom you are indebted for them. Let it be your ambition as well as your prayer that you may be ever animated by the spirit of that great and solemn obligation which the philosopher and physician, Hippocrates, the Father of Medicine, required from his pupils—"In purity and holiness I will spend my life and practise my art." Do this, and then

> "Shall inferior eyes,
> That borrow their behaviour from the great,
> Grow great by your example."

Lectures ON PRACTICAL LEGAL MEDICINE.

Being the Post-Graduate Course delivered at St. Mary's Hospital,

BY AUGUSTUS J. PEPPER, M.S. LOND.,
LATE EXAMINER IN FORENSIC MEDICINE TO THE UNIVERSITY OF LONDON.

LECTURE III.

GENTLEMEN,—In the first place let me direct your attention to the post-mortem appearances of the stomach and intestines in certain forms of natural and violent death. It is often very difficult to distinguish the *congestion of the stomach* incidental to disease and prolonged vomiting from that due to irritation of the mucous membrane by poison. In very pronounced cases of either, of course the question is easy of determination, and in these, too, the concomitant signs, together with the history, place the matter beyond doubt. But there are many instances in which, on casual and exclusive observation, a wrong interpretation may be made. I believe, however, it seldom or never occurs that

[1] On Abdominal Section. By Sir William Mac Cormac. Annual Oration delivered before the Medical Society of London, 1887.

Digitized by Google

one is unable to arrive at a definite conclusion. Nevertheless, one meets occasionally with a case which at first sight is very equivocal and liable to be misconstrued for want of sufficient consideration of the possible results of physiological and pathological factors. On a previous occasion, when speaking of congestion of the brain, I mentioned a prevalent error—viz., confounding the causes of death with the modes of dying. A similar mistake is sometimes made with regard to congestion of the stomach. Passive congestion or venous engorgement of the stomach is found after asphyxial death, and also when there has been obstruction of the portal circulation. So, too, the veins are filled to repletion when a person has died during active digestion. The force of gravitation causes the blood to accumulate in the large veins in the cardiac end of the stomach, so that the difference in colour at the cardiac and pyloric portions is very marked—so much so that it may excite a suspicion that an irritant poison has been administered; but in irritant poisoning, besides the venous congestion, the mucous membrane is marked by more or less intense capillary injection. There is a diffused or punctate redness of a bright vermilion tint over a dark bluish-black arborescent background. Acute gastritis of extrinsic origin may closely simulate the condition of the stomach when inflamed, as the result of the action of some general morbid state—e.g., the specific fevers. In the latter, however, the injection of the mucous membrane is, as a rule, more evenly and widely distributed; and in one particular affection—typhoid fever—the solitary lymphoid glands are enlarged in like manner as they are in the intestine. This latter sign should not be overlooked. In two instances within my knowledge it furnished a clue as to the ultimate cause of death, which was unsuspected during life. In the first case, a boy aged twelve died somewhat suddenly in hospital from profuse hæmorrhage from the stomach. At the necropsy the mucous membrane of the stomach was injected and the solitary glands were markedly swollen. One of these had ulcerated into a contiguous artery. The intestinal glands showed that the disease was of about eight days' duration. You might ask how could a mistake arise in the investigation of such a case? At the general post-mortem examination one would not be likely to make one; but suppose the stomach had been removed and sent to you for examination, you might not be furnished with the corroborative evidence afforded by the intestine and the mesenteric glands. The second of the two cases above referred to was that of a girl, aged six years, who died in February, 1886, after being attacked with vomiting, which lasted thirty-three hours. Diarrhœa set in eighteen hours before death. The symptoms were singularly like those of irritant poisoning, and the post-mortem signs observed in the stomach seemed consistent with this theory. The mucous membrane was generally hyperæmic, the entire surface being redder than normal. This was most marked in the cardiac portion, for reasons mentioned above. There were groups of capillary extravasations of blood in the mucous and submucous tissues. The solitary glands were enlarged, and the summits of a few contiguous rugæ on the posterior surface were blackened. The recollection of the enlargement of the lymphoid glands seen in the former case led me to surmise that here also I might be dealing with the consequences—primary and secondary—of typhoid fever, and so it turned out to be, for typical enteric lesions existed in both the mesenteric and intestinal glands. From an examination of the stomach alone, I believe it would have been difficult to say that the deceased child had not succumbed to the effects of an irritant poison taken into the stomach. The sequence of events was much as follows: the mucous membrane of the stomach was inflamed from the specific poison of typhoid fever; this was followed by a very natural consequence—persistent vomiting; the vomiting caused serious interference with the gastric circulation—to such an extent, in truth, that the tension in the capillaries led here and there to rupture of their walls, and thus to the punctate extravasations. The black streaks spoken of deserve special mention, because they might have been taken as signs of superficial corrosion of the mucous membrane; but on close inspection it could be easily seen that the epithelial surface was not broken, nor had the membrane lost its natural lustre. This was rendered more obvious by the passage of a stream of water over the area involved. The staining was not due to hæmorrhage, for, although recent, it was quite black; moreover, it was in the form of uniform splashes along the tops of the rugæ. There can be little doubt that some metallic bismuth had been deposited on the membrane after death, when the muscular coat was contracted and the mucous coat thrown into ridges, for to allay the vomiting a salt of bismuth had been prescribed for and taken by the patient. A careful analysis of the contents of the stomach revealed a trace of bismuth. It is interesting to note that in this case—one of suspected irritant poisoning—allowance had to be made for the possible presence of three metals given medicinally—viz., bismuth and cerium as stomachic sedatives, and mercury as an aperient. It was feared that by accident the child might have taken a poisonous dose of a mixture which contained arsenic and iron. Nothing but bismuth was detected. Before dismissing the present inquiry, let me emphasise the fact that capillary extravasations into the mucous membrane of the stomach are frequently caused by the act of vomiting, irrespective of organic changes in the mucous membrane. It is an important matter, and worthy of your best attention. Not seldom I have heard it stated that such extravasations were strongly suggestive of irritant poisoning. Taken by themselves, let me repeat, they are of little forensic value.

I pass now to the consideration of certain features of intestinal lesions that not unfrequently come under the notice of the medical jurist. A person is seized, perhaps unexpectedly and suddenly, with violent vomiting and pain in the abdomen. Nothing is known that can throw light on the case. The usual remedies are given, and fail. Death ensues, say, within twenty-four or thirty-six hours. It is not surprising that suspicions of foul play should arise, and it is your duty to dispel or confirm what before the post-mortem examination was only conjecture. Let me cite to you one or two cases by way of illustration. A strong, healthy, middle-aged man was seized with uncontrollable vomiting, accompanied by griping pain in the abdomen. The symptoms continued with but little variation until his death about twenty-five hours afterwards. An inquest was held, and a post-mortem examination was made by two medical men. They found the mucous membrane of the stomach markedly congested, and a portion of the small intestine so injected with blood that even the outer surface presented a deep crimson colour. Coupling these facts with the symptoms and their pronounced course during life, they came to the conclusion that an irritant poison had been taken accidentally or administered by design, and gave the cause of death as being "congestion of the stomach and peritonitis." I was requested to make a further examination of the cadaver. This was done in the presence of three medical men. I pointed out that the nature of the congestion of the stomach was such as is met with after prolonged vomiting. The veins were full, and there were groups of punctate extravasations, but an absence of general minute injection of the vessels. Moreover, there was no abrasion of the mucous membrane. Then, again, the portion of small intestine that had suffered was not continuous with the stomach, but several feet below it, the intervening portion of bowel showing no abnormal appearance. It was not probable that an irritant poison would affect the stomach and then pass a large section of the bowel unscathed to spend its action on a number of coils below, and there end as abruptly as it had commenced. Fortunately the state of the peritoneum gave the desired supplementary evidence. The mesentery corresponding to the congested bowel was studded with patches of extravasated blood, varying from the size of a hemp-seed to that of a sixpence. All doubt was now dispersed—the case was one of twist of the bowel, a condition explaining each and all of the symptoms and post-mortem signs, phenomena consistent with no other hypothesis. I may remark that the volvulus had been reduced at the first examination, so that I did not actually see it. The case illustrates the way in which facts may be misinterpreted, and shows further how a previous manipulation, though properly conducted, may destroy evidence of the greatest value.

Let me now give you briefly the facts of another case of suspected poisoning, in which death was due to acute obstruction of the bowel from traction on the small intestine by adhesion bands, the result of an attack of general peritonitis of distant date. The deceased was a soldier, aged twenty-four. Prior to his fatal illness he was not known to have suffered from any serious organic disease. It is true he had had syphilis, but this had yielded to appropriate treatment. One morning he was seized with griping pains in the abdo-

Digitized by Google

men, vomiting, and great thirst, followed shortly by cramps in the legs. He died exhausted in about eighteen hours. I was not present at the first examination of the body, nor at the first sitting of the coroner's court. The medical men who had charge of the case found the stomach and a portion of the small intestine much congested, especially the latter. They gave an opinion that the deceased might have succumbed to irritant poisoning. I was ordered to make a further investigation by way of post-mortem inspection and chemical analysis. The latter procedure failed to detect any kind of irritant or corrosive poison; in fact, the results obtained were purely negative. A careful examination of the contents of the abdomen left no reasonable doubt as to the cause of death. The congestion of the stomach was not sufficiently pronounced as to render it the probable cause of the violent vomiting and the rapidly fatal course of the symptoms generally. There were numerous peritoneal adhesion bands, concerning which I need only particularise two. One of these was stretched across the sigmoid flexure of the rectum, and had exerted considerable traction on an adjacent coil of intestine. No untoward results had ensued from this; but the second band had constricted a coil of the small intestine to such an extent, that for the length of a foot its lumen had become enlarged to many times its normal size. The mucous membrane in this portion was quite pale, but above it there was intense but uniform congestion, evidently of mechanical origin. There was no corrosion of the mucous membrane, no abrasions, and no hæmorrhages. The limitation of the congestion below was very distinct, as though a piece of cord had been tied round the bowel. I have little doubt that the affected coil of intestine had become suddenly twisted upon the fixed point of adhesion. The congestion from an irritant poison is never so abruptly defined nor so completely and evenly diffused without other abnormal appearances. The mesenteric glands were enlarged and caseous, but there was no evidence anywhere of active tubercular mischief.

Now, one occasionally meets with instances of death from obstruction of the bowels in which the symptoms are mild and of correspondingly long duration. They may be so little marked, in fact, that their cause may be overlooked, and even at the necropsy the signs of obstruction may appear inadequate to explain the death. I refer to the cases of partial strangulation of large herniæ in *old people* with little vital power. The reflex centres do not respond promptly and with energy to the peripheral irritation, but participate in the general subdued tone of the whole nervous system; and at the same time the patient's strength is unequal to support the strain expressed in terms of pain and emesis of moderate severity. I will give you a typical instance which came under my notice in the present year. An aged man had for several days complained of some pain in the stomach, and this was followed by vomiting. He was admitted to hospital, and died eight hours later from exhaustion. During life the house-surgeon disengaged from an inguinal sac about a foot and a half of small intestine, which I found moderately congested, but presenting nothing like the appearance usually found where death has been caused by strangulation of the bowel. Besides this, there had been no difficulty whatever in reducing the hernia by taxis. Previous experience enabled me to affirm that the deceased owed his death to obstruction of the hernial protrusion. The case affords evidence, if it were required, of the necessity of examining all known hernial sites when the abdominal symptoms, however slight, are in any way doubtful.

I will now direct your attention to the consideration of some comparatively rare causes of death which may be overlooked for want of information respecting the actual state of health of persons prior to their sudden decease. In the first place, let us glance at the condition known as *diabetic coma*. It is not my purpose here to analyse in detail and make a differential diagnosis of the peculiar state above indicated, but I may parenthetically remark that faculty-consciousness is not necessarily present, as has been supposed, in all cases. Nor, according to my experience, is it usual for the diabetic halitus to be abolished or perceptibly diminished during any stage of the period of unconsciousness. In short I look upon its presence as the great safeguard against confounding diabetic coma with other forms of insensibility during life, and against falling into error as regards the cause of death. Of course it is quite plain sailing where the malady is known to have existed beforehand, and in such no excuse can be made for diagnostic or forensic blunders. But I want to impress upon you the necessity, when making a post-mortem examination in a case of death from coma concerning which none of the antecedent conditions are known, to note the odour that emanates from the tissues and viscera. You should direct your observation especially to the *brain*, because, in the first place, the peculiar and characteristic smell of diabetes is there well exhibited; and, secondly, inasmuch as it is not masked by other odours such as one meets with in the abdominal viscera. It is scarcely necessary to mention that you should preserve any urine that may be found in the bladder post mortem, and any that may have been voided during the fatal illness of the deceased person. On two occasions I have been able to demonstrate the cause of death of individuals who during life were not suspected of having suffered from any disease. In each case a *sectio cadaveris* had been performed without discovering that the body gave off what appeared to me as the highly marked and characteristic smell of acetonæmia. People, like animals, vary much in their discriminating power of detecting various odours, so we must not expect too much from this means of gathering evidence. We must be on our guard that the smell of acetonæmic tissues is not mistaken for the sweet odour incidental to pyæmia and other less defined pathological states. Even if you suspect death from diabetic coma on the grounds that a peculiar emanation is given off from the fluids and tissues, you will not rest contented with the suspicion, but analyse the urine or cerebro-spinal fluid both for grape sugar and the derivate body alleged to be acetone. Finally, I may add that if a person presumably healthy beforehand is found dying from coma, and if after death no coarse anatomical lesion is found sufficient to explain the event, you should at once note acetonæmia as a possible, nay, even probable, explanation. If neither sugar, acetone, nor any other poison is discovered, it is not unlikely that the deceased succumbed to epilepsy. You know the first attack may prove the last, so that, save for a family history of neuroses, there may be nothing to guide the medical jurist.

A few words with regard to sudden death from *saturnine epilepsy*. It is curious that a body so chemically simple as lead should bring about such curious, I might almost say mysterious, phenomena. There can be no doubt that workers in the metal far more frequently suffer from cerebral symptoms than is generally supposed; and I believe that death is not so rare from epileptiform convulsions of saturnine origin as our text-books on forensic medicine would lead us to believe. It is all very well to teach that lead workers can with ordinary care steer clear of danger; but from observations I have made—and my opinions are corroborated by medical men in charge of lead factories—it is extremely difficult to prevent the metal gaining access to the system. I once heard it sworn in court that over 90 per cent. of the white-lead workers in a particularly well-conducted factory showed the blue line in the gums. In one case I examined the husband of a woman who had fallen a victim to "lead epilepsy." He had been employed for only three months in making litharge, and yet his gums were discoloured almost as much as I have ever seen. This man assured me he had carried out most faithfully all the precautions enjoined by his employers, and which, moreover, were those which the law demanded should be given. In cases of supposed death from saturnine epilepsy, it is necessary to examine the gums, the intestines, and the nervous system, and to make a chemical analysis of the viscera, especially the liver. Just one word of caution about the staining of the gums. Do not jump to the conclusion that because the gums are blue they are necessarily so from deposit of lead. I have known simple post-mortem congestion of the mucous membrane in question closely resemble lead staining; nay, I have seen it mistaken for it. The dark venous hue of the blood is toned down to a steely grey by the thick white epidermis. But you can always avoid error by applying a simple chemical test. The blue line of lead is turned yellow by chromic acid, and hydric sulphide converts the yellow into black. You are told the intestines are found contracted (post mortem) in chronic lead-poisoning. This is not always the case. I have found them free from contraction, but then one may observe the general hypertrophy of the muscular coat of the bowel, and the absence of permanent mechanical obstruction.

There is yet another cause of comparatively sudden death that may be overlooked—viz., *Addison's disease*. In the only case of the kind that came under my notice, the real condition was not discovered at the necropsy.

Digitized by Google

The inquest was adjourned for further inquiry, and I was directed to examine the body. I found the suprarenals tubercular, and pigmentation of the skin well marked. The deceased had suffered from general ill-health and progressive emaciation, but the particular affection had not been recognised.

In concluding this lecture, I will direct your attention to a source of danger to life which, so far as I know, has not hitherto been noticed in the medical press. I refer to *poisoning from the use of perchloride of mercury in the form of very weak solutions*—e.g., 1 in 1500 or 2000. I understand that in midwifery practice it is not at all uncommon to employ injections of the strength just mentioned for cleansing purposes, not only as a corrective against septic discharges, but also as a prophylactic. Where the patient is free from organic disease of the kidneys one has little need to fear untoward consequences from the treatment under consideration. I am aware of two cases of death from acute inflammation of the bowels following closely on the injection of very weak mercurial solutions into the vagina shortly after parturition. As in each instance no other cause of the fatal complication could be discovered, there is little doubt that the acute irritative lesions in the intestines were due to the perchloride in the course of its elimination. The action of the salt was concentrated, so to speak, in this particular region by reason of grave renal affection. In one of the two cases I made a very exhaustive post-mortem examination. The whole of the small and large intestine was acutely inflamed. There were thousands of hæmorrhagic patches, punctate and irregular in shape. There were a few minute recent ulcers. The catarrhal congestion was extreme. Lymph was effused into the substance and upon the surface of the mucous membrane. Slight general peritonitis seemed to have started at the middle of the colon, where the intestinal lesion was more marked than elsewhere. The stomach was not affected. The kidneys were in an advanced state of fatty degeneration. No aperients had been administered to the patient, but a solution of bichloride of mercury (1 in 2000) had been injected into the vagina to prevent decomposition of the lochia. Profuse diarrhœa ensued, and continued until death. The body temperature was never raised, and latterly it was subnormal. I was at a loss to account for the ultimate cause of the diarrhœa and its fatal consequences until the circumstances were explained to me by an obstetric physician who was present at the necropsy, and who had witnessed a precisely similar case in his own practice. The lesson to be learnt from the foregoing narrative is—that even a very attenuated solution of a mercurial salt should not be employed as a vaginal injection without first ascertaining the state of the kidneys by an examination of the urine.

ON SIMPLE DILATATION OF THE STOMACH, OR GASTROECTASIS.[1]

BY T. C. ALLBUTT, M.D. CANTAB., F.R.C.P. LOND., F.R.S.

MR. PRESIDENT AND GENTLEMEN,—When your honorary secretary, Dr. Samuel West, invited me to read a paper before the Medical Society, and enhanced this compliment by inviting me to read the first paper of this session, he tempted me with too great a temptation. I frankly admit that I grasped at the honour without duly considering whether I had anything to say which should justify my coming before you thus to occupy your time and attention. My first suggestion, a proposal to read some notes on pneumothorax, I withdrew in a panic as soon as I had read Dr. West's own most excellent essay thereon. My second proposal, which I fulfil by bringing the present paper before you to-night, seemed to be justified by my abundance of cases and notes of gastroectasis. These I have carefully gone over, and find, when it is too late to change my subject, that I have no conclusions to offer you which are not already known. May I hope that if I take you again over facts and doctrines previously known, I take you over a subject not too familiar.

In the course of practice I find that the diagnosis of simple gastroectasis is often overlooked; nay more, that when pointed out the malady is not readily recognised. Indeed, two or three years after I wrote my first paper on the subject in 1879, I was assured by a physician of great eminence that he had not before heard of gastroectasis as a primary malady, and having heard was indisposed to admit the existence of it. My own enlarged experience has, however, not only fortified me in the diagnosis of such cases and confirmed their reality, but has impressed me with their frequency. That which at one time I regarded as a special and unusual clinical phenomenon I now recognise as one of common observation; for gastroectasis, which, in its fully established form, is a prominent and unmistakable malady, enters in less degree into many modes of dyspepsia, debility, and tissue failures, and claims in its degree due recognition and treatment.

To clear the ground, permit me in the first instance to say that the limits of my subject to-night exclude all cases of secondary gastroectasis. Secondary gastroectasis as a result of pyloric obstruction of organic origin, whether cicatricial, invasive, or otherwise, I put on one side, and propose to speak only of simple ectasis due to the predominance of pressure upon the inner surface over the resistance of the walls of the stomach, such pressure not being accumulated by pyloric obstruction. Indeed, it is not necessary to suppose that in such predominance the sum of the pressure upon the internal surface of the stomach is absolutely increased. It is obvious that this predominance could be established if, that pressure remaining the same, the resistance of the walls were diminished. Doubtless you are prepared to hear me say that in the majority of cases of simple gastroectasis this morbid state is more often due to failure of resistance than to excessive pressure within. Two painful cases illustrating this position spring into my memory; they were brother and sister, and both were frail persons. In them also occurred that connexion between phthisis and acute rheumatism, upon which I have often insisted.

A young lady, having passed through rheumatic fever of a somewhat adynamic type, soon afterwards was attacked by acute tuberculosis. The family history was phthisical. Scarcely had the phthisis become very manifest when acute dilatation of the stomach set in, and her latter days were rendered grievous indeed by the suffering which this entailed. Not many months passed by when her brother, a slight young man of about twenty-six years of age, was seized with acute rheumatism. We suspected him of ulcerative endocarditis, so intractable and adynamic was the course of the disease. However, he slowly recovered. But no sooner had he entered upon convalescence than we discovered a large gastroectasis, which miserably delayed his recovery and sapped his nutrition and vitality. Ultimately, I believe, he has attained to some sort of health, but for two or three years the dilated stomach resisted all means of cure, and I have not seen the patient since. These two cases, among many others, illustrate, then, with more than ordinary clearness, the admitted occurrence of gastroectasis, due not to accumulated pressure, nor indeed to any absolute increase of pressure within, but to diminished resistance without.

These two cases were as easy to observe and to describe as they were difficult to treat, because they were extreme cases. That dilatation of the stomach from enfeebled tone occurs in a very large number of weakly persons, or as an item of suffering in a very large number of enfeebling maladies, is an assertion I venture to make from the results of much investigation and inquiry, but is nevertheless one which is as difficult to demonstrate to you now as the extreme cases are easy, because the degrees of it are far less, and because its symptoms have been hidden under generalities like atonic dyspepsia, nervous debility, and so forth. A watchful diagnosis will, however, detect this morbid change amid other signs and symptoms, and deal with it by special means; for it may be found under like conditions from the suckling to the adult, though less often in old age. In all fevers, whether adynamic in type or not, gastroectasis may occur, and often does occur. Where the temperatures run high for some time, it seems probable that even in robuster persons some reduction of the muscular value of the coats of the stomach would occur, and I am in the habit of observing the state of the stomach in the course of such maladies. Thus I often detect degrees of ectasis, be they more or less, and find it desirable to regulate the management of the cases accordingly. Of course, in the vast majority of them recovery takes place readily enough, whether the ectasis be detected or not. Weight at the epigastrium, a rejection of mucus, water, or wind, a retardation of amendment, a caprice or dulness of

appetite, a coated tongue, fretful or low spirits, and, above all, a slackening of flesh, direct us to the stomach, when percussion and palpation confirm the former suspicion. Happily, for other reasons, the dietary in such cases has generally been limited, and thus the labour of the stomach economised. In phthisis the existence of gastroectasis is far more common than is generally supposed. I ought to have taken statistics on this question, which would have been easy enough in chamber practice; as it is, I can only offer you the inconclusive proof of my own undefined experience, and ask you to watch the matter for yourselves. Two of my cases of phthisis treated in Switzerland, and another case treated on the sea, were terribly retarded by higher degrees of dilatation of the stomach. All these cases were otherwise of a very hopeful kind, and two of them have made fair recovery; the third died solely because of the gastroectasis, which thwarted all our efforts to advance his nutrition. In these cases I must say that I do not speak of advanced or prominent dilatation, but of a degree which can be detected by careful examination, and the symptoms of which are chiefly pain, impaired nutrition, and nervous depression. To such persons the dietary of seagoing vessels and of hotels is often very harmful, and their cry of dyspeptic suffering ascends without ceasing.

In infants and young children dilatation of the stomach is constantly overlooked, and I have nowhere seen a proper estimate of this complication of children's maladies.[2] In sucklings the affection is not confined to the hand-fed, but may be found in the breast-fed when the tone of the digestive machinery is lowered. In them abnormal decomposition of food readily sets in, as we too well know—one of the first functional changes being a retardation of the rate of digestion, and a retention of the food three or even four times as long in the stomach as it ought to be there. The epigastrium protrudes and tightens; the stools grow costive, pale, and offensive; the child becomes fretful, rejects sour mucus and altered food, and its flesh falls rapidly. By palpation and percussion a dilated stomach is often found to be present—not as a varying and transitory phenomenon, but as an enduring pathological change,—less difficult to cure than in older persons (for children soon grow out of their maladies), but bad enough to keep the child back for months.

In these and like cases, both in children and in adults, I am anxious to put this before you—that although the gastroectasis may be but one part of a more general malady, or may even be but a by-phenomenon, yet it is always a factor to be counted with, and one to be treated for itself. Catarrh of the stomach is often present, of course, at the same time, and may be a main cause, as it is always an aggravation, of ectasis; yet catarrh may exist (and very commonly does exist) without ectasis, and we ought in all cases to ascertain as far as possible the degree of both or of either. I urge this not only for the rational treatment of such cases on their appearance, but because the gastroectasis may survive the acuter stages and become later the substantial lesion. One very bad case of this kind was brought to me two years ago in a child of three to four years old, born in India, and whose vital powers and nutrition were much enfeebled. In it gastroectasis had presented itself as the main pathological factor. About the same time a boy of ten was brought to me in whom I discovered gastroectasis of the complete clinical type, with all Kussmaul's and Leube's symptoms, and needing persistent washing out. The history was obscure, but there was no definite history of primary catarrh, rather one of neglected ill-health and careless nutrition. In a far-gone case like this the prognosis is very grave, if not despairing; had the condition been recognised sooner recovery would have been certainly secured.

Besides febrile and exhausting diseases, there are other causes of gastroectasis from diminished resistance, the modes of some of them being clear enough, of others more obscure. The clearest of these is gastric catarrh, the tendency of which to weaken parietal resistance is too obvious to detain us. Less easy to explain, though not of the obscurest, are such causes as failing absorption, chronic venous congestion of the stomach, failing digestive secretions, and the like. When absorption fails, we understand that retention of ingesta and their gases, by increasing pressure, adds to the effect of simple yielding of the parietes. In heart disease and cirrhosis of the liver, for instance, [illegible] when venous stasis increases on the walls of the stomach, defective absorption, with delay of fluid, semifluid and gaseous contents, is probably the main cause of the distension of the stomach, which is so troublesome a complication in these cases. In them, although distension be common, troublesome, and enduring enough, yet it rarely passes beyond the first or second degree, which seems to indicate that delayed contents and diminished absorption do not produce voluminous ectasis unless there be a conspiring muscular enfeeblement of the walls themselves. For we know that even in many cases of pyloric obstruction, and of considerable obstruction, the stomach may retain its normal volume or go not beyond a moderate degree of amplitude, and in these we find the muscular coat hypertrophied—hypertrophied sometimes to a measure which indicates an extraordinary sum of pressures upon the inner surface. But owing either to the nature of the patient, or to the course of the malady, which has given time for compensation, or to some causes less understood, the concentric tendencies have not been overpowered. In one case of stricture of the pylorus by scar of ulcer, even after repeated attacks of large, acute and most agonising gastroectasis, the stomach so pulled itself together that on a necropsy some months later the greatly overgrown muscular walls seemed to bound a cavity rather under than over the average volume. This process of retraction could be followed tolerably well during life, and, finally, the small striving sac visible through the emaciated abdomen declared beforehand the revelations of the post-mortem table. Pain and hæmorrhage had dictated a sparing and special dietary for a long time, and thus the acute distensions were prevented. But this by the way, to show what can come about. Of the obscurer causes of failing gastric wall are those classed as nervous. It is said that the stomach may be palsied, or lose much of its nervous life or stimulus, as the limbs may, either by its own isolated misfortune or sharing in a more general stroke. Of direct palsies of the stomach, lighter or heavier, I can tell you nothing; nor do I know much of those indirect submissions of its muscular power which may be explained by loss of innervation, and are thus inessential. We can remember, however, a very large class of cases in which general neurasthenia, or nervous weaknesses or distresses springing from the region of the digestive organs and thence invading and depressing the whole being, are associated with marked gastroectasis; but whether the nerve lesion or the lesion of the stomach be primary is one of those questions which I ought to have been able to justify myself by answering to-night, but which I cannot answer. Suffice it to point out the frequent, nay the common, connexion between gastroectasis and a large and fairly constant group of nervous symptoms and sensations, a group variously called hypochondriasis or hysteria according to its conditions. That under some strange gusts of nervous temper the stomach of a woman, or even of some men, may become distended like a balloon and yet soon collapse again, suffering no permanent injury, is amazing. In these pyloric incontinence probably prevents any permanent injury. The dilated stomach of a so-called hipped man is, however, a graver matter, for in him the organ is often found to be permanently enlarged, and its reduction a matter of difficulty or even impossibility. In some of these cases no doubt the stomach lesion came first and the general misery followed, but in others one strongly suspects that the stomach has yielded because of some defect of innervation more special to itself. The distressing epigastric symptoms in these cases, the tenderness there, and the [illegible] other symptoms tempt us to suspect an affection of the great abdominal nervous ganglia, but our knowledge of their functions and changes is far too rudimentary to justify any such speculations at present.

Thus far have I dealt most slightly with some causes of gastroectasis due to failure of normal resistance. But gastroectasis may be induced, no doubt, by excessive pressure upon the inner surfaces of the organ, even in cases where the pyloric opening is intact. Prolonged or immoderate irritation of the cavity, as by the habits of the common glutton, produces a certain and even a considerable amplitude of that organ. But in a robust and well-fed animal this enlargement is rather a development than a retrogression, and I have no definite recollection of such a case ending in a bad form of the disorder. That which belongs gastroectasis to its graver and irremediable degree is ordinarily at once bulky or coarse and innutritious. Bad cases of chronic gastroectasis not due to exhausting [illegible] are chiefly found

[illegible] Vide Epstein, quoted below.

among the working classes, and in them the malady in its well-marked form is far from uncommon. Miners, engine drivers, piecework ers and the like, men generally of the most respectable and hardworking sort, too often find themselves before middle life with a large gastroectasis. These men have no regular meal hours, and, indeed, for many hours together have no leisure for a meal. If they have time to feed, the meal may consist of some coarse and indigestible stuff, washed down, it may be, with pints of tea. You would not believe me did I tell you the number and capacity of the cans of tea which these men may empty in a day. Thus, the stomach is not only overloaded, but is charged with a solution which in such quantity is directly mischievous to digestion and probably to the stomach itself. Flatulent dyspepsia, unnoticed at first, adds its inflation to the rest, the sufferer fails to understand the evil of his ways, the stomach gets worse, nutrition then suffers and dilatation follows, this result being partly due to the local pressure, partly to irregular functional activity, and partly to general impoverishment of the blood, each factor intensifying the other. The abuse of aerated waters, again, in more than one case, seemed to be the cause of well-marked and obstinate gastroectasis; and I have had reason to think that a vegetarian diet has brought about the same result. I once discovered a gastroectasis of large dimensions in a middle-aged lady of the upper classes, who had consumed inordinate quantities of effervescing waters. She absolutely repelled the very notion of washing out, and she ultimately recovered on dietetic and medicinal treatment. In her, I believe, some atony of the *primæ viæ* existed, as she came in later years under my care for fæcal accumulation in the transverse colon. Dilatation of the stomach is, I think, much less common in women, perhaps because they eat less or eat more regularly; but in them exhausting discharges are a potent cause of the malady, and in them, as in the male sex also, neglected hæmorrhoidal losses may have this effect.

I will now venture to make a few remarks upon the *symptoms* of dilatation of the stomach. And first let me preach this precept urgently—that in all cases of dyspeptic troubles the stomach be carefully mapped out. Even if but temporary dilatation exist, it is important that it should be known and dealt with. A man once consulted me who was in the way of seeing many doctors in his regular engagements, and had been prescribed for by nearly as many with little result. He called upon me, and I found dilated stomach, probably of no long standing. I cut off fluids and flatulent food, and he made a rapid recovery, and remains well. But a dilated stomach may more certainly be suspected if a wearing, aching pain abide in the pit of the stomach, if there be foul or acid eructations and marked emaciation.

Vomiting is not invariable. Some people have not the knack of vomiting; in others the walls of the stomach may be too flaccid to aid in the rejection of its contents; in others, where the stomach is hypertrophied in its mucous and muscular coats, as in gorging eaters, absorption and peristalsis may be fairly good. In such cases physical signs must be sought for. In better-marked cases the vomiting is often thus characteristic—that the stomach rejects its contents, generally voluminous contents, as a pump ejects water; the refuse comes forth in a rushing stream, often without any nausea whatever, and often at tidal intervals, which may be very long, may be as long as two days, but generally are less than that. In such cases we always see a drawn face, a worn and pained expression, and an emaciating body. The patients complain of constant wearing pain about the waist, relieved by the vomiting.[3] The vomit may sometimes be mere catarrhal matter, phlegm and water, and is not then pathognomonic, but it is most commonly what we call in Yorkshire "swill"—i.e., a turbid sour liquid containing remnants of half-dissolved food in a state of active fermentation. It is usually dark in colour, and swarms with sarcinous and other low forms of life. Stir up the materials of a day's meals, add dirty water and catarrhal slime to it, set it aside at a temperature of 100° for a few hours, and thereafter froth it up with a stick, and you will have the foul vomit of gastroectasis. The stomach, like an incompetent urinary bladder, never really empties itself, however vigorous the vomiting, and the fetid remnant carries forward the process of decomposition to all that is swallowed. The physical signs of this state when so complete are clear enough. The emaciated abdominal wall; the sac beneath it, quite perceptible to the hand lightly stretched over the surface, and often to the eye; peristalsis also visible perhaps if the muscular coat be hypertrophied (this more commonly in pyloric obstruction);[4] splashing and succussion areas—all agree in declaring the diagnosis. I have seen on post-mortem examination the stomach dilated to the pubes. But all cases are not so easy. Sounds not to be well distinguished from splashing and succussion may be got in persons not known to have dilated stomachs; in neurotic subjects of borborygmatous tendencies this is not uncommon; but these in the latter are to be got only by kneading, never by shaking or swaying the body with the hands upon the crests of the ilia; the sounds, too, are got with more difficulty, and are not so marked. On the other hand, even in dilated stomach, splashing is often not aroused by the first manipulation, but when once aroused is loud enough, and easy to continue. In neurotic girls false splashing is often to be obtained by causing them to inspire deeply; indeed, I have seen this squashy sound associated with ordinary inspirations in such persons, and in these it will be noticed that the respiration is not so much thoracic as diaphragmatic.

Of percussion I will only remind the observer that the upper line, which in acute or early cases, before the whole stomach is dragged downward, may reach to the fourth or even to the third rib, is at least as important as the lower. If the lower line be below the umbilical, a dilated stomach may, I think, be certified. Whether the percussion sound be metallic, tympanitic, or even muffled, I think, is of no diagnostic value, so that it is often difficult to be sure from the quality of the sound whether we are tapping stomach or bowel. Tapping with a plexameter while the stethoscope is on the stomach is sometimes a help.

Another caution is this—that in certain cases of relaxed gastro-phrenic ligament the whole stomach may be displaced downwards; hence the importance of ascertaining the *upper* line. With all possible care, however, thus far dilatation may not be ascertained or may not be measurable. Hence we have to resort to other physical aids, of which the development of gas in the stomach by the ingestion of effervescing salines is the best known.[5] By this means the area may be mapped out, and as the gas passes away the line of fluid contents may also be mapped out. It must be remembered in the less severe cases that a *displacement* of the stomach *downwards* when filling betrays so far a *dilatation*, as the normal stomach in filling should rotate forward. Leube's sound is well known, and indicates the lower margin of the stomach, either by its perception through the abdominal walls or by its length from the teeth, which Penzoldt says should never be more than one-third of the height of the body. I have not verified this statement. All I can say is that the sound should never be felt below the umbilicus, and if a pint and a half of water (thirty ounces) be injected the dulness should not fall below that point. My judgment upon this sounding is that in thin subjects we rarely need it, and in fatter ones the point is indistinct. Even in these cases, however, if a ball bellows be affixed to a hollow sound a gurgling may be made in the stagnant contents and their site detected, or the viscus distended with air so far as to reveal its size and form. Thiébaut, in an excellent monograph (Paris, 1882), suggests that a plumb-line ending in a lead may be worked through a hollow sound. This I have not tried. Distending gases should be expressed from the stomach before the plummet or sound is used. The elimination of pyloric disease from the diagnosis must depend on other considerations, and must not now detain us. Nor need I detain you with any account of the pathological anatomy of gastroectasis, which is well known. The dimensions of the cavity are sometimes enormous. Blumenthal found the vomited matter alone in one case to weigh 16 lb. A common increase is to about four times the normal cubic contents—i.e., an increase up to about six quarts. Simple dilatations may be quite as extensive as a dilatation secondary to pyloric disease.

As regards treatment, I shall set aside all general and pharmaceutical means, and refer to three main special methods, which are—(1) to cleanse the stomach; (2) to prevent its distension by physical or chemical means; and (3) to combat the prevalent constipation. I must premise that dilatation of the stomach, when it has

[3] Dr. Fenwick, I think, rather underates this pain or distress (Quain's Dictionary).

[4] Peristalsis may sometimes be made visible by rapidly alternating warm and cold currents of water through the stomach by means of the syphon.

[5] Bicarbonate of soda, 6 gr.; tartaric acid, 4 gr.; to be drunk off at once with two tumblers of water.

Digitized by Google

reached a well-marked degree, is a most difficult disease to cure. The patient's condition may be made much more tolerable and his nutrition improved; some cases may be ultimately cured; but too often, after all, "prævalebunt fata consiliis." The *constipation* tends to prevent both absorption and the free passage of intestinal contents. It is best overcome by portal purgatives, such as the laxative salines. As the stomach recovers tone the costiveness becomes less obstinate; I presume the bowels then receive more reflex stimulation. The dietary must be strictly limited to such foods as shall not, by bulk or by decomposition, distend the stomach. Meals must be small, if frequent, and must consist of flesh, fish or fowl, and the more digestible and finely divided fats. Dr. Fenwick even recommends cod-liver oil. Farinaceous foods cannot be wholly forbidden, but, owing to their tendency to gaseous decomposition must be greatly restricted. I have always urged that the dietary should be as dry as possible, but I see Dr. Fenwick recommends liquid food. I am sure liquid should at any rate be restricted, and tea, beer, aerated waters and the like, forbidden. Small quantities of pure but diluted spirit are useful. Vegetables must be wholly replaced by a little lemon juice. Milk, I think, is often used too freely in these cases. As the peptic glands are often reduced or obliterated, artificial digestive means should not be forgotten. But all these precautionary means are useless if we drop our food into the foul puddle which the dilated stomach never wholly throws off. Dr. Fenwick, to whose great authority on these questions I am wont to defer, speaks with disappointment and mistrust of the only known means of cleansing the gastric receptacle—namely, Kussmaul's system of washing out. This troublesome and disgusting performance offends the more refined and sensitive class of patients, and in dealing with them the physician is too soon persuaded to lay aside or altogether to forbear the use of the stomach-pump. But gastroectasis is far more common in the less-refined and more roughly-fed members of society. They show less repugnance to the washing-out method, and in them, therefore, its excellent results become more evident. A thorough conviction of the essential value of this treatment in hospital and working-class patients strengthens me in insisting upon its use in all such sufferers. Some patients flatly decline to have anything to do with the process; but in others, less prejudiced, a little practice and use soon brings toleration. A few have thrown up the plan in disgust after a few trials, but so many continue it patiently, in spite of trouble and disgust, as to testify not only to the purifying powers of the method, but to the unspeakable relief which it brings to present distress. To deny the catheter to the palsied stomach seems to me as unreasonable, and in practice is as great a blunder, as to deny it to the palsied bladder. Yet, familiarly as the practice is now known in and around Leeds, I believe it is but little used in English practice generally. My own experience of washing out in dilatation of the stomach has been equalled, perhaps, by few living physicians, and I have never known any ill result from it. Among other cases I may refer especially to the many under our care in the Leeds Infirmary, which Dr. Jacob and Dr. Barrs, now our colleagues, used during their term of residence so assiduously to wash out. I have never seen the cramps or tetany recorded in a few cases of washing out by Kussmaul himself, and again lately by Dujardin-Beaumetz;[6] but it requires, no doubt, great determination and patience to carry out the plan over the necessarily long duration of time required for permanent relief. In Virchow's *Jahres-Bericht* for 1883, Epstein is reported to have obtained great success in washing out the stomachs of dyspeptic infants under one year old. His experience extended over 286 cases, and is published in the *Arch. f. Kinderheilkunde* (Bd. iv., S. 325). He uses a No. 8-10 Nélaton's catheter, and warm water with a little benzoate of magnesia, and relieves catarrh, wasting dyspepsia, &c. As a means of diagnosis, I find that in purely nervous dyspepsia (so called) the stomach between meals contains no remnants of food, no fungi, no excess of hydrochloric acid and mucus, but from this starting-point one may begin to note all degrees of catarrh and ectasis. Plain warm water is, I fancy, all that is required for the ablution, though I generally suggest the addition of a little borax to the wash. In the beginning of treatment, when the contents of the stomach are bulky and lumpy, it is well to use the stomach-pump. It is said that the suction of this instrument may and does wound the mucous membrane. If so, I have never seen any harm from this, nor do I hear that harm resulted in the cases wherein wounds were said to have been made. With a large lateral opening in the tube and careful exhaustion there is practically no likelihood of harm. For subsequent treatment, when the stomach contents are clearer and less bulky, a syphon is simpler, and, moreover, if filled with a reservoir, can be used by the patient himself. The cistern must be placed just above the level of the head and attached to the flow-pipe, and an exit-pipe must be carried to a pail on the floor. By pinching the flow-pipe the patient can easily regulate the flow. As I have already hinted, the œsophageal tube should have a spacious oval opening on the side of it, a little away from the rounded tip. These tubes are foolishly made, as a rule, with the tip perforated by several finer holes. Such tubes block directly, and dishearten both doctor and patient. I have some very intelligent patients who have thus washed themselves out daily for a year or two or more, with unspeakable relief to their sufferings, rapid improvement of nutrition up to a certain point, and a slow recovery of the stomach itself. Other remedial means, such as the use of antiseptic and other drugs and of nutrient enemata, I have not time now to discuss. Of electricity, however, I must say this: that it has greatly disappointed my expectations in whatever mode or however applied. The external application of faradism and of massage to the abdomen are, nevertheless, well worth a trial; though I suspect they have only the value of general faradisation and general massage, or are worthless. A cushion pad, supported by a bandage, should always be worn, and Leube directs his patients to lie as much as possible, and that on the right side only.

A REPORT OF CASES (SURGICAL AND MEDICAL).

BY J. HARRIS JONES, L.R.C.P. EDIN., L.F.P.S. GLASG.

EXTRA-UTERINE PREGNANCY.

I SUPPOSE it is scarcely necessary to offer any apology for bringing the following case before the profession. The subject of extra-uterine pregnancy has always been one of great interest, and seldom does an opportunity offer itself to a practitioner to watch and treat a case of this kind with such good results as the subsequent history will disclose.

On the night of October 21st, 1885, I was hurriedly called to see M. E——, a married lady, aged about twenty-seven. Upon inquiry, I gathered from her that she had been married a little over six years, but had never been pregnant. Her menses, since their first appearance when she was fourteen, had always been irregular and painful. About two weeks previously to being seen she became "unwell," and, contrary to her usual habit, the flow had persisted ever since. She had been attending to her household duties all along, and had lately been unusually busy at dressmaking, which necessitated her using the sewing machine (a pedal movement one) for several hours daily. She had been compelled to go to bed and send for me in consequence of having been taken with a violent pain low down in the right iliac region. The pain was paroxysmal in character, and made her feel very faint and sick at the stomach. I carefully examined the painful region, but could detect nothing abnormal there save that deep pressure increased the pain. On examination per vaginam, it was noticed that the os and cervix uteri were unusually soft and flexible, but there was neither tenderness nor fulness discoverable in any part. A semi-sanguineous fluid was seen issuing from the wound. A subcutaneous injection of a quarter of a grain of morphia was administered, and turpentine stupes were ordered to be applied over the abdomen. Next morning I called again to see her, and found that she had slept many hours during the night. She was not, however, completely free from pain. Another injection of morphia (one-eighth of a grain) was given, and a mixture containing the oxalate of cerium was prescribed for the nausea. The thermometer in the axilla registered 99·5°. Under this treatment she rapidly improved, and in a few days was well enough to leave her bed, and I discontinued my visits. She was cautioned against taking

Digitized by Google

undue exercise, and if the pain recurred she was requested to send for me immediately.

She remained in tolerably fair health until Nov. 17th, when I was again summoned to see her. I found her suffering in a precisely similar manner as before. Her face presented a very blanched appearance, and it was quite evident that she was suffering either from shock, produced by the severity of the pain, or that an internal hæmorrhage was occurring. No evidence of the existence of the latter could be satisfactorily diagnosed. She was treated as before, and advised to remain perfectly at rest in bed. Being of a very active temperament, I found it difficult to keep her quiet; but having explained the evil results that might arise from exercise, she reluctantly consented to remain in her bedroom. I visited her almost daily, and on each occasion carefully examined the painful "side," but nothing abnormal could be detected. The discharge from the vagina was diminishing, and by the 1st of December it had completely stopped. On the 4th of that month, upon percussing the iliac region a heavy dull sound was detected immediately above Poupart's ligament, and palpation revealed the presence of a growth there. Nothing, however, could be learnt from a vaginal examination. The fulness increased in area, and it was not many days before it had ascended a couple of inches above the point first noted. Indeed, after the second week of discovery the fulness became very apparent, and it was easy to recognise that the enlargement was daily becoming more pronounced. Her general health remained good, and, with the exception of nausea and an occasional attack of vomiting, she had little to complain of. I was in much doubt at this period as to the nature of the enlargement, hesitating between an hæmatocele and an extra-uterine pregnancy. I applied the stethoscope to the swelling daily after my first discovery of the growth, but no sound of any kind could be heard over it. On Jan. 15th, at my request, Dr. E. R. Mayer, of this city, saw the case with me, and after making an examination and taking into consideration the condition of the cervix uteri and the existence of a swelling in the iliac fossa, accompanied by nausea and cessation of menstruation, he was inclined to believe that the case might be one of extra-uterine pregnancy, and advised that electricity be tried; and should the swelling eventually prove to be due to a hæmatocele or an inflammatory effusion, the treatment would in either case be appropriate, and perhaps beneficial. Eight days after this consultation, I heard, for the first time, over the growth a distinct blowing murmur. It was not a sharp and an acute sound like that caused by the pulsation of a bloodvessel underlying a tumour, but a deliberate and diffused murmur very much resembling the placental bruit, which I had no doubt it was. Dr. Mayer saw the case with me on Jan. 27th. The blowing murmur was distintly heard by him. Neither of us after this had any doubt as to the patient's condition. Treatment by electricity was commenced, one electrode being introduced into the vagina and the other placed over the tumour. The operation lasted about ten minutes. I pursued this treatment daily, and before and after every *séance* made it a point to listen to the bruit with my stethoscope. I found that the sound was very much intensified after using the battery. After a fortnight's perseverance with this treatment, and finding no appreciable change in the growth, I was about despairing of its utility in extra-uterine pregnancy. The tumour, when electricity was first applied to it, had reached to within an inch of the umbilicus, and had just crossed over beyond the mesian line. The placental souffle was much weaker on Feb. 17th, and was not increased after using the battery. On the 18th no sound of any kind could be heard over the tumour. The battery was not employed after the 17th. After this I contented myself with simply watching developments, hoping that the amniotic fluid would be absorbed, and the fœtus converted into a lithopædion. In this I was disappointed. In the course of a few days the growth appeared to be getting larger and its contents softer. The patient's health rapidly failed, profuse sweating set in, she became feverish and chilly alternately, and had a temperature of about 101°. I was satisfied that the contents of the sac were undergoing maceration, and that the patient was becoming septicæmic. A consultation was held with Dr. Mayer and Dr. G. H. Guthrie, and it was decided that the patient's only chance of recovery lay in the operation of laparotomy and the removal of the offending material. A uterine sound was inserted for about two inches into the womb. Much difficulty was experienced in passing the instrument, owing to the body of the womb having been pushed to the opposite side by the tumour. There was no fulness to be felt in any portion of the vaginal roof. The operation was performed on March 11th, twenty-two days after the death of the fœtus. Drs. Mayer, Guthrie, Davis, and Long very kindly assisted. Ether was used as an anæsthetic, and its administration was entrusted to Dr. Long.

Operation.—The abdomen was washed with a solution of carbolic acid, and I commenced the incision one inch below the umbilicus, and extended it downwards for about three inches and a half, directly in the median line. Considering the emaciated condition of the patient, there was a very thick layer of subcutaneous adipose tissue. After the recti muscles had been reached and separated, the tissues beneath were very much ecchymosed, and it was impossible to recognise any of the structures. The peritoneum, though not recognised as such, was greatly thickened. The sac was clearly exposed to view. It was of a chocolate-brown colour. An incision was made into its lower border and extended in an upward direction for about three inches. It was fully an inch in thickness at its base, but became quite thin towards the apex. Its cut edges were of a dark-brown colour, and looked very much like leather. The hand was introduced, and the placenta, which was on the surface and floating in fetid pus, was readily recognised by its peculiar granular feel. Its edge having been reached, the hand was pushed beyond it, and the fœtus (a male, measuring about ten inches) extracted. The placenta, being already completely separated from its attachments, was taken away immediately after. No portion of intestine was seen, and there was scarcely any hæmorrhage at any stage of the operation. It was feared that the adhesions to the inner surface of the abdominal parietes on the left side of the sac were not very secure, consequently the latter was secured by sutures to the corresponding wall of the abdominal incision. The sac was thoroughly cleansed with a weak solution of carbolic acid, and to prevent the enormous gaping of the wound, two stitches were inserted through the tissues of the abdominal wound and the sac. A glass drainage tube was introduced, and a thick layer of antiseptic cotton was placed over the wound and secured by a bandage.

The patient rapidly rallied from the operation. She vomited freely for several hours. A very spare allowance of iced champagne and milk was given for the first few days. The sac was syringed out night and morning. On the sixth day after the operation a fluid resembling bile was observed in the discharge from the wound, and on the following day white particles were seen mixed with it; these were evidently portions of curd. The bowels were moved spontaneously. It was now suspected that a communication existed between the intestines and the external wound. As the latter granulated from the bottom, a portion of intestine, presumably the jejunum, was lifted into view, and an opening was distinctly seen in it. The bowels continued to act very indifferently for many months, sometimes only once in two or three weeks; occasionally they would act weekly or semi-weekly. The discharge from the opening in the intestine was very great on some days; it was generally of a semi-liquid character, but never fæcal in odour. With this exception, my patient was doing nicely and rapidly gaining in weight. The temperature never exceeded 100° F. after the operation. The sac was rather slow in granulating, and it was fully seven months before the granulations reached to the level of the surrounding skin. The discharge from the intestine diminished *pari passu* with the filling up of the sac. When the abdominal wound had completely healed and cicatrised, there remained for several months a small fistula, which occasionally discharged a little fluid, just enough to slightly moisten the dressing placed over it. At present the patient is quite well, and weighs more than she ever did. Menstruation is regular and painless, and the contents of the bowels have been passing entirely *per vias naturales* for many months.

Remarks.—If this case had been left alone to nature, is it likely that labour would advance to full term, and thus give the attending surgeon an opportunity to deliver a living child by an abdominal incision? This is a question that has repeatedly suggested itself to me. It is of course difficult, and even impossible, to speculate upon the final result of a non-interfering or expectant plan of treatment. The probabilities are that the sac, which was very thin at its apex, would have certainly given way as its contents enlarged, and, judging from its appearance when seen

Digitized by Google

during the operation, the rupture would undoubtedly soon occur into the bowels, stomach, or liver. Indeed, I think that the opening seen some days after the operation in the bowel was the result of a commencing erosion. When did conception occur? Was it tubal, ovarian, or abdominal? I think in all probability it was tubal, but that at a very early period the ovum made its escape intact into the peritoneal cavity, and there appropriated for its own use additional investments from the neighbouring tissues. Menstruation had always been very painful to the patient, and much soreness was felt in the right iliac region during her periods. It is therefore probable that a catarrhal affection of the right Fallopian tube existed, and that a denudation of its epithelium had occurred, accompanied, perhaps, by a dilatation or sacculation of the canal; or a stricture of the canal might have existed. Either of these conditions would favour the arrest of the ovum in its downward course to the womb. How did electricity destroy fœtal life in this case? Believing that the bruit heard over the tumour was caused by the circulation of blood in the centre of the placenta—i.e., in that portion where the umbilical cord is attached to it, and where the bloodvessels congregate to form the main trunks,—and observing that the murmur was always intensified after using the battery, I am inclined to think that death resulted from rupture of the over-distended bloodvessels of the placenta; in other words, that a form of placental apoplexy was induced by the current.

(To be concluded.)

CASE OF

TRAUMATIC TETANUS; RECOVERY.

By JAMES MILNER, M.R.C.S.

CASES of the above, terminating in recovery, are sufficiently rare to merit placing on record when they do occur. I therefore venture to publish the notes of the following case:—

T. S.——, aged twenty-seven, a brickmaker's labourer, came to the surgery on June 28th, complaining of stiffness about the jaws and inability to open the mouth, together with stiffness of the right leg, and difficulty in flexing that leg upon the thigh. There was marked risus. Upon inquiry it was found that four days previously—i.e., on the 24th, he noticed that one of the nails of his boot had penetrated the sole and wounded the pulp of the right great toe. The punctured wound which resulted had almost healed, but the parts around were somewhat sensitive. Tetanus was diagnosed, and bromide of potassium in fifteen-grain doses every four hours was prescribed.

On the following morning he again presented himself, stating that the stiffness about the jaws had increased, as also had the difficulty in opening the mouth. Moreover, he complained of stiffness about the back of the neck, with shooting pains down the back. He was ordered to remain in bed, and thirty grains of chloral hydrate were given; the bromide of potassium to be continued as before. Liquid nourishment only could be given, as with the greatest effort the mouth could only be opened sufficiently to allow of an ordinary cedar pencil being inserted between the two rows of incisor teeth. A wooden wedge was secured between the teeth, so as to prevent the jaws closing still further. Seen later, there was found to be marked opisthotonos, the spasms being attended by considerable pain. Chloral hydrate in forty-grain doses was ordered every night, and thirty grains every morning, and the bromide of potassium to be continued as before. The treatment above mentioned was followed out for a week, and every care was taken to remove all sources of irritation to the over-sensitive patient. The room was darkened and kept as quiet as could be, a screen was placed round the bed so as to exclude currents of air, and every other precaution which suggested itself was strictly observed. The case, however, continued to progress unfavourably, and the patient was becoming exhausted. It was now evident that the treatment was almost powerless to control the disease; consequently it was decided to have recourse to surgical interference. Accordingly, on July 6th, a deep incision was made in the toe, around the nail-bed and about a third of an inch from it, so as to divide the nerves leading to the cicatrix as far as possible. Linseed poultices were then ordered to be applied to the toe. On the following day, the spasms were found to be decidedly less in severity and frequency, and day by day they continued steadily to decline, with the exception of one occasion about a fortnight after the incision, when an attempt was made to leave off the chloral hydrate by omitting the morning draught. On this day the spasms were more severe than they had been for some days previously. It was therefore evident that the reflex excitability of the cord was still much above normal, consequently the chloral was recommenced. At this time the patient was troubled by a somewhat violent hiccough, which continued, with very short intervals between the attacks, for some forty-eight hours. After this a steady recovery ensued, and seven weeks from the commencement of the disease the doses of chloral hydrate were gradually diminished, and a week later it was entirely left off, a full week having elapsed since the appearance of the most trifling spasm. The bromide of potassium was continued for another three weeks, during which time out-door exercise was allowed.

With regard to this case, although I do not think the incision alone would have been sufficient to complete the cure, as the spasms increased when, during the course of the disease, an attempt was made to discontinue the medicinal treatment, still I do think that without the incision death must inevitably have ensued, seeing that the bromide and large doses of chloral hydrate seemed absolutely powerless to check the excessive reflex excitability of the cord, whilst the source of peripheral irritation remained.

Hayes, Middlesex.

COMMUNICATION OF SYPHILIS BY TATTOOING.

By GRENVILLE E. MOFFET, M.B. ABERD.,
SURGEON, ARMY MEDICAL STAFF.

THE extreme rarity of this mode of communicating syphilis induces me to publish the following cases. The subject, apart from its etiological bearing, will, I think, have a special interest for military and naval surgeons, when we consider that at least nine-tenths of our soldiers and sailors voluntarily submit themselves to the operation of tattooing.

Case I.—C. M——, a gunner, R.A., aged twenty-one years, was admitted into hospital on Aug. 31st, 1885, with an ulcer over a tattoo mark on the anterior aspect of the left forearm, two inches below the elbow. The ulcer was about the size of a shilling, very painful, with indurated edges and base; it was surrounded with a circumscribed areola of inflammation, and its surface was covered with a scanty puriform exudation. The axillary epitrochlear and sub-occipital glands were indurated, and there was a specific roseolar rash over the chest, back, and arms, accompanied with sore throat.

Previous history.—Patient was tattooed at the end of December, 1884. About the end of March, 1885, he noticed "a small hard pimple" over the site indicated. Beyond being a little itchy this gave him no further trouble, and he thought no more about it. Two months before admission the patient scratched the pimple, and thus converted it into a "sore," which, under his own treatment, gradually increased in size, became very painful, and presented, on admission, the appearances described above. About a week before admission the patient noticed a rash on his body, and felt his throat sore. This man's "medical history sheet" (a document which accompanies every soldier throughout his service) showed two previous admissions for venereal disease (February and April, 1883), but, according to the notes made by the surgeon who treated the patient on both these occasions, the sores were local, soft, and unaccompanied with general induration of glands; but a suppurating bubo followed the first infection. The treatment was also local, and the patient was discharged from hospital after a residence of forty-one and fourteen days respectively.

On the present occasion the treatment consisted in the local application of black wash, and subsequently iodoform, and the internal administration of mercury. The sore healed in about three weeks, leaving a depressed, copper-coloured cicatrix. The rash and throat symptoms had also quite disappeared by this time. The mercury was, however, continued (ten-drop doses of the tincture of perchloride of iron being also given three times a day), till the patient was discharged from hospital on Oct. 3rd.

Digitized by Google

CASE 2.—Trumpeter J. G——, aged fifteen years, was admitted into hospital on Sept. 17th, 1885, with an ulcer the size of a sixpence over a tattoo mark on the anterior aspect of right forearm. The ulcer resembled so nearly that described in Case 1 that any detailed description would be merely a recapitulation of what has already been said above. The boy also had a sore throat, and his trunk and extremities were covered with a distinctly papular syphilide, which he only noticed about ten days before admission.

Previous history.—This boy was tattooed in Londonderry by a soldier, on Oct. 12th, 1884, with needles which a few hours previously had been used on other soldiers for the same purpose. His medical history sheet shows no previous admission to hospital. The boy was only twelve years old when he enlisted, so that he could scarcely have acquired syphilis before enlistment. There was no history of syphilis, and careful examination of the penis revealed no marks of sores. In December, 1884, the patient noticed "a small hard lump" over the site indicated, but as it gave him no trouble, he took no notice of it till about six weeks before admission, when it became larger, more painful, and a watery discharge exuded from it, causing a scab to form over its surface. The boy removed the scab as it formed, and dressed the sore with some "salve" which he got from a local chemist, but finding that it got worse every day, he came to the hospital. The treatment was similar to that pursued in Case 1. The ulcer had healed in a fortnight, and the patient was discharged on Oct. 12th, by which time the rash and sore throat had quite disappeared. On Dec. 17th he was readmitted, the rash and sore throat having returned, but under specific treatment both disappeared, and the patient was discharged after a residence of ten days in hospital, with an injunction to return as soon as the rash reappeared, or he felt his throat sore.

CASE 3.—Gunner W. C——, aged twenty-seven, was admitted to hospital on Sept. 25th, 1885, with an ulcer over a tattoo mark below the insertion of the right deltoid muscle. It was about the size of a sixpence, painful, and its surface was covered with a foul-looking slough; its base and edges were not so indurated as in the last two cases, but there was an area of induration in the cellular tissue immediately surrounding it. The axillary and epitrochlear glands were enlarged and indurated.

Previous history.—Patient was in hospital in Dec. 1883, at which time he had three sores on the prepuce followed by a suppurating bubo. The sores were treated locally, the bubo opened, and the patient discharged in twenty-four days. He has not been in hospital since till the present admission. This man was tattooed in January, 1885. The following April he noticed a small hard pimple over the spot, the history of which was very much the same as that of Case 2. It gradually got larger, and became so painful, that he was obliged at last to come to the hospital.

The slough was first removed by poultices, after which the local and general treatment was the same as that detailed in Case 1. The ulcer had healed by Oct. 19th; on the 28th a roseolar rash, preceded by slight febrile disturbance and sore throat, appeared on the trunk and arms. Mercury was discontinued, a saline purgative and warm bath ordered. Two days afterwards calomel baths were begun, and continued every second night till the rash had quite disappeared. The tincture of perchloride of iron was given at the same time, and continued till the patient's discharge from hospital on Dec. 28th.

Remarks.—The only reference to this subject that I have been able to find is in Lancereaux's treatise, where that eminent authority merely alludes to the possibility of communication in this way, and refers to a paper by Petry of Vienna on the Transmission of Secondary Syphilis by Tattooing. There seems little doubt that the disease in the above cases was conveyed during the operation of tattooing through the medium of needles which had been previously used on other soldiers affected with syphilis. The history of Case 2 seems quite clear, but that of Cases 1 and 3 is not, at first sight so evident, owing to the previous admissions for venereal disease. The surgeons who treated the patients at the time state the disease to have been local. In both, the sores were without induration, multiple, followed by suppurating buboes, and, though treated without mercury, were not followed by any secondary symptoms during two years or more after infection. Both men, however, after being tattooed presented, within a given time, all the local signs of syphilis, followed in each case, about five months (?) after the development of the papule, by well-marked secondary symptoms. I think, therefore, that everything is in favour of the view that the disease was communicated by the operation.

There is one point which calls for notice in these cases—viz., the periods of incubation, which seem to have been of rather longer duration than usual. The secondary symptoms also were of a very mild type, and Lancereaux says that "the longer the period of incubation is, the milder are the manifestations of the general infection." It is, however, on the testimony of the patients as to the first appearance of the papules that the determination of the period of incubation hangs, and none of them could give any precise information on this point. Bearing this in mind, and also the possibility of the presence of induration at the points of inoculation *before* it had attracted any notice on the part of the men, I am inclined to believe that the periods of incubation were not prolonged in any of the cases, but rather that the mildness of the general infection was due to the communication of the disease from a secondary lesion, and probably in some degree dependent on the modes of infection.

Gibraltar.

A CASE OF

ACUTE PNEUMONIA IN AN ALCOHOLIC PATIENT IN WHICH THE DELIRIUM OCCURRED CHIEFLY AFTER THE CRISIS.

BY WALTER H. HAW, B.A., M.R.C.S., L.S.A.

A. B——, aged forty-seven, married, a labourer, came into the surgery on the evening of June 3rd, 1887, with the following history. On the evening of May 31st he was exposed to the wet for several hours. On arriving home he went to bed, feeling perfectly well. The next morning, on rising, he had a shivering fit, but did not discontinue his work, in spite of a pricking pain in the region of the right nipple. The next day (June 2nd) the shivering fit was repeated, and lasted for a considerable time; the thoracic pain still continued. On June 3rd he had a third rigor. In the evening of this day he walked briskly into the surgery, but on standing he appeared rather shaky. A history of alcohol was elicited later from his wife, the patient repudiating the idea.

The following are the notes of the man's condition taken at the time:—There is a double patch of herpes about his mouth; one on the right side of the upper lip, and the other in a corresponding position on the lower. Digestive system: Tongue slightly furred, but moist; teeth greatly discoloured; appetite bad; no nausea or vomiting; bowels regular. Vascular system: First sound muffled, second accentuated at the base; no enlargement; no murmur; pulse 120, full, bounding, and compressible; visible pulsation in the arteries of the neck and arms. Respiratory system: Breathing slightly hurried, the inspiratory act not being fully performed. There is cough, with slight frothy expectoration, not rusty, and pain referred to a point one inch below the right nipple. On examination of the chest, nothing abnormal was detected by inspection and the other usual methods, except slight increase in frequency of respiration, and short inspiration. Abdomen normal. Urine febrile, depositing lithates; no albumen. Cutaneous system: Skin dry and hot, but the face is perspiring freely. Temperature 104° F., but the patient says he feels no inconvenience.

The patient was ordered to bed and put on a strictly supporting treatment.

June 4th.—Patient found sitting in front of the fire downstairs. No further rigors. Sleeps and takes food well, and is anxious to get back to work. Temperature 104°; pulse 120; respiration slightly hurried. Bowels acted twice.—5th: Still shaky, but pain in side better. Slept well. Herpes disappearing. No delirium at night. Temperature 105°; pulse 120. Skin of body dry; face moist. Ordered ten grains of sulphate of quinine, to be repeated in four hours.—6th: Slept well. He says that yesterday he dressed himself and went downstairs without any reason. Temperature 104·5°; pulse 132, not so bounding; respiration 22; pulse respiration ratio 6:1. Distinct pneumonic signs are now apparent below the right clavicle, with fine crepitation at the end of inspiration. The consolidation is chiefly in the

Digitized by Google

anterior part of the right apex. Lungs apparently normal elsewhere, and the pain in the region of the nipple has disappeared. He says he feels better.—7th: Looks worse; is lightheaded and wandering. Temperature 104·4°; respiration 24; pulse 124; ratio 5:1 nearly. He is quite rational when spoken to, and says he sleeps and takes his nourishment well. Auscultatory signs slightly more distinct.—8th: Looks better. Temperature 102·6°; pulse 114; respiration 24. Lightheadedness more marked, and patient answers at random. Signs at apex clearer. Dulness very marked, and the crepitation less, but tubular breathing is more apparent. Nourishment &c. taken well.—9th: Appears better. Temperature not taken, my thermometer having unfortunately been broken; respiration easy; pulse slightly above normal. Mental condition that of delirium tremens.—10th: Mental state worse, but no sedative was ordered as yet. Temperature and respiration normal.—11th: Mental condition accentuated. Patient was found seated in the doorway, and on being questioned as to the reason, he explained that it was the nearest way back to bed. He also measures the articles of furniture in the room, and is suffering from muscular tremors. Tongue moist and slightly furred. A sedative draught of chloral and bromide was ordered every four hours. Temperature and respiration normal, as also pulse.—13th: After the second dose of sedative mixture a sound sleep was obtained. Looks better, and is quieter. Speaks rationally. The dulness below the clavicle is not so marked, but the crepitation is still distinct, and the vocal resonance is increased. Temperature &c. normal.—24th: Since the above note the progress of the case was uniform, both as regards the mental and the lung condition, and the man is now quite well.

Remarks.—There are, I think, one or two points of interest in this case. 1. The lung lesion was situated in the anterior part of the right apex. This occurs rather frequently in patients who have become debilitated from any cause, and especially in those whose tissues are damaged by alcohol. 2. There were three distinct rigors on successive days. This is, I believe, uncommon in the invasion of acute pneumonia, there being usually, as is well known, one sharp initial rigor, except in the case of children and old people, when this symptom may be, and is usually, absent. The crop of herpetic eruption bore no proportion to the severity of the rigors. 3. The high temperature (104°), with no particular subjective symptoms. 4. It is interesting to note that the mental change and the lung lesion were simultaneous in their appearance on the sixth day of the fever, and seemed afterwards to progress almost *pari passu*, each commencing just before the crisis, continuing for some time, and then gradually disappearing, the delirium being the first to vanish, but probably the sedative given effected this. I think the appearance of the lung lesion directly determined the onset of the delirium, the patient being a robust man, and, in spite of his alcoholic indulgence, being able to withstand the effects of the fever to a certain extent. Thus the pulmonary lesion proved the last straw, and helped to prolong the delirium into the period after the crisis.

ST. THOMAS'S HOSPITAL.

ACUTE PERITONITIS FROM PERFORATION OF AN ULCER OF THE GALL-BLADDER; NECROPSY.—INTESTINAL OBSTRUCTION CAUSED BY STRANGULATION OF A DIAPHRAGMATIC HERNIA; NECROPSY.

(Under the care of DR. ORD.)

ULCERATION of the gall-bladder leading to perforation and a fatal peritonitis is not of common occurrence, and in the following account there are several points worthy of notice. Although gall-stones may be met with at any age, they are rare at twenty-three (out of 305 cases collected by Hein only fifteen were below the age of twenty-five). It will be observed that the perforation was not preceded by any symptoms of the presence of a stone in the gall-bladder; this, however, was the probable cause for the ulceration, though in the majority of published cases there was more than *one* stone. The patient was difficult to control, but was improving under judicious treatment with perfect rest, until the sudden movement which she made on the 26th, when the weak adhesions were probably broken down, giving further exit to the bile, thus starting the acute general inflammation of the peritoneum which terminated fatally on the 28th. The patient with diaphragmatic hernia was in such a condition of collapse on admission that no operative measure was permissible, although such was discussed. There was no history of injury, neither was there history of attacks of gastro-intestinal disturbance as described in some cases; the symptoms developed suddenly and without warning. In this case there was no regular sac to the hernia, and omentum as well as large intestine had passed through an opening of small size. For the notes of the case we are indebted to Mr. H. J. Macevoy, house physician.

CASE 1. *Acute peritonitis from perforation of an ulcer of the gall-bladder; necropsy.*—B. B——, aged twenty-three, single, general servant, was admitted on June 21st, 1887. Family history good. The patient had rheumatic fever eight months ago; had pleurisy in April, 1887, and was treated at Guy's for a month. She states that she went to bed after a late supper, feeling perfectly well, on the evening of June 17th, and was suddenly attacked with severe abdominal pain, increased by movement and pressure. She also vomited almost at once, the first vomit being "dark," the next green. The pain and vomiting have continued up to admission. Bowels well opened on the 17th, not since. There was blood in the urine on the morning of admission, but the patient is menstruating.

On admission, at 7.30 P.M., she appeared to be a healthy, well-nourished girl, with an anxious and painful expression, complaining of abdominal pain and tenderness, and vomiting. Skin cold and clammy about hands and feet; forehead cool and perspiring slightly. Pulse 120, hard and regular. Respirations hurried and shallow. Tongue moist, and coated with thin brown fur. Temperature 99°. Lungs normal. There was a faint systolic bruit at the base of the heart. Abdomen with moderate uniform distension, and moving only slightly with respiration; generally tender (not acutely), especially on the right side; percussion note tympanitic, with the exception of some dulness in both flanks; no thrill; no obvious peristalsis; no tumour felt. Urine: Only a little passed; sp. gr. 1022, acid, one-fifth albumen. A quarter of a grain of morphia every two hours was ordered, and glycerine and belladonna applied to the abdomen.—12.30 midnight: Patient was sick almost constantly up to 10.30 P.M. Less tenderness of abdomen. Pulse 132, tense. Pupils slightly contracted. Ice given to suck. The morphia was increased to one-third of a grain every two hours.

June 22nd.—2 A.M.: No hiccough; no sickness. Flatulence. Rather more restless, and craving for drink.—11 A.M.: Sick three times since 2 o'clock; vomit dark green. Tongue moist; little brown fur. Complains of headache. Pulse 120, full and regular. Temperature 100·6°. Light palpation of the abdomen easily borne. Nutrient enemata given and retained. Nothing by mouth but ice to suck.

23rd.—No vomiting. Tongue moist. Pulse 136. Temperature 102·4°. Urine: Albumen one-half; indigo; no blood. To take one-third of a grain of morphia every three hours only.

24th.—No vomiting. Abdomen: Resonance less tympanitic; moves a little more with respiration; only slight tenderness on right side; none elsewhere. Pulse 132; temperature 102·6°. Tongue rather dry. Increase of albumen in the urine. To have morphia every four hours only; a teaspoonful of milk and a teaspoonful of brandy every quarter of an hour.

25th.—No vomiting. Abdomen not tender, and little less distended; no peristalsis. General appearance improved. Pulse 132. Tongue moister.

26th.—After improving a little during the day the patient was taken suddenly worse at 7 P.M., after swallowing two ounces of milk which she took off her locker. She vomited about two teaspoonfuls of dark-green fluid with coagulated milk, became excited, and struggled in bed. Temperature 102·8°. Ordered one-third of a grain of morphia every two hours instead of every four hours. Pulse 160, difficult to count, weak and thready.

Digitized by Google

27th.—Slept badly. Delirious. Subsultus in hands. Abdomen not altered. Temperature 102·2°. Pulse can scarcely be felt. Tongue moist. Urine half albumen.

After this she became more and more restless and delirious, and struggled and shrieked, her delirium taking a maniacal form. She died at 4 A.M. on June 28th.

Necropsy.—On opening the abdominal cavity, several pints of fluid were found in it, stained with bile, light brown in colour, and without fæcal odour. The coils of intestine were glued together, covered with patches of thick fibrin, and much congested. No ulceration or perforation of intestines. The liver was noticed to be attached by recent inflammatory products to the colon, but nothing further could be found until the liver was removed. The gall-bladder was found to be collapsed, and a diverticulum projected from it on the left. On opening it, a black, round, mulberry-surfaced gall-stone, about the size of a large pea, was found in it, freely movable. The upper part of the gall-bladder, where it rested on the under surface of the liver, was the seat of an ulcer with sharp edges, evidently chronic. It was adherent to the liver, and the wall of the bladder appeared to have been destroyed. At one place the adhesions had given way, and an orifice into which the blade of the scalpel might be passed was present, which had evidently given exit to the contents of the gall-bladder. No gall-stone was found free in the peritoneum. The other organs were healthy.

CASE 2. *Intestinal obstruction caused by strangulation of a diaphragmatic hernia; necropsy.*—J. W——, aged thirty-seven, coachman, was admitted on July 7th, 1887. Family history good. The man had been a hard drinker. Has enjoyed good health. Bowels generally regular. He was suddenly seized while lying on the grass on July 1st with severe twisting pain in the abdomen, which caused him to roll about; he vomited repeatedly on the next day, the vomit becoming gradually offensive. The pain has been more or less present up to admission, but the vomiting is less, and not constant after food. Bowels were opened well and naturally on the 1st, then a few scybala were passed on the 6th. Flatus was expelled, however, in the meanwhile.

On admission at 3 A.M. he was noticed to be a robust man, fully conscious and answering questions rationally, but intensely collapsed. Breathing rapid and shallow; forehead and extremities bathed with cold sweat; hands and feet icy cold; face and lips livid. Tongue moist, and covered with thin dirty-white fur. Breath of a peculiar sweet and sickly odour. Temperature 98; pulse 136, weak. Abdomen much distended, especially in its right and upper parts, and perfectly motionless during respiration. Slight dulness in the right flank, but general over-resonance, notably in the left iliac fossa and left hypochondrium. No peristalsis visible; no marked tenderness. Ordered a quarter of a grain of morphia hypodermically every two hours, and a teaspoonful of milk by the mouth frequently.—11 A.M.: The patient vomited some dark-brown fluid, not stercoraceous or particularly offensive, at 8 o'clock. He complains of abdominal pain, but there is no tenderness. Still signs of collapse. Urine: Sp. gr. 1020; acid; trace of albumen. Temperature 101·8°.—1.30 P.M.: A little brown liquid passed per anum, containing some mucus; pain and straining while at stool. After this delirium gradually came on, assuming the form of alcoholic delirium; he became violent, had a fit of convulsions at about 4 P.M., and died shortly afterwards.

Necropsy.—On opening the abdomen, which was greatly distended, no peritonitis was found; but there was enormous distension of the transverse and ascending colon and cæcum, and the bowel in these regions was of a purple colour. The descending colon was collapsed, pointing clearly to an obstruction at the splenic flexure of the colon. The small intestines were of moderate size, and likewise the stomach, which was pushed out of sight by the distended colon. The obstruction was found to be due to the passage of a knuckle of colon with a large mass of omentum through a hole in the centre of the left half of the diaphragm, and to its becoming strangulated. The orifice in the diaphragm appeared very small, and, judging by the character of the adhesions of the gut to it, which were not recent, one would conclude that the hernia had been in existence some time. There was some inflammation of the solitary glands in the large intestine behind the obstruction, but no ulceration. The lower part of the left pleura was acutely inflamed, and much lymph covered the lower lobe of the left lung. From half a pint to a pint of fluid was found in the left pleural cavity. The lower lobe of the left lung was collapsed. Heart, liver, brain, and kidneys healthy. There was no evidence of fractured ribs or other injury which could account for the orifice in the diaphragm.

EDINBURGH ROYAL INFIRMARY.

FOUR RARE FORMS OF DISLOCATION.

(Under the care of Mr. A. G. MILLER.)

THE following are notes of some of the more interesting dislocations which were under treatment when Mr. George Hardyman, M.B., C.M., was resident surgeon, and we are indebted to him for the account.

CASE 1.—P. L——, aged nineteen, a soldier, fell from the Argyle Battery of Edinburgh Castle into Prince's-street Gardens, a distance of about 150 feet, on June 1st, 1887. The tibia and fibula of the left leg were severely comminuted, but there was no compound fracture. There was a dislocation of the right knee. The right tibia and fibula were dislocated outwards, so that the external condyle of the femur rested on the internal facet of the tibia. The internal condyle of the femur was very prominent and easily felt, extending freely beyond the internal ridge of the tibia. The external lateral ligaments were apparently entirely ruptured, while about one-third of the internal lateral ligaments was left unruptured. The dislocation was reduced under chloroform by extension and manipulation with the thumb. The leg was then put up in extension with a weight and pulley. There was great effusion into the joint, which was reduced by means of ice followed by pressure. On June 26th, a posterior and an internal poroplastic splint were put on, and on July 9th the knee was put up in starch. On Aug. 10th, three weeks after he had left the hospital, he was going about without any artificial support, except a starch bandage over the knee.

CASE 2.—A. B——, aged twelve, fell from a height of about two feet forwards on his head. When seen, there was found on the dorsum of the radio-carpal region a prominent well-defined swelling, which on inspection gave the impression that there was a fracture of the lower end of the radius. However, on manipulation the rounded, well-defined ridge caused by the proximal extremities of the carpal bones could be made out. This was easily reduced by extension, and after reduction there was discovered a green-stick fracture of the radius as well. The tendons on the palmar aspect were not ruptured, as happened in another case which has since been brought under notice by Dr. H. A. Thompson. The after treatment gave no trouble.

CASE 3.—A middle-aged man was admitted on Aug. 27th, 1887. He was then cold and unconscious, breathing heavily, with the pupils unequal, one pin's point, and insensible to light. He could be roused with difficulty by a painful sensation sufficiently to utter a grunt. He lived eight hours after admission. He was supposed to have fallen about seventy feet from Arthur's Seat, and to have remained where he fell for some hours, as he was quite wet from rain which had fallen some hours previously. He had what appeared exactly like a fractured humerus at the junction of its upper and middle thirds, but on manipulation it was found that there was a subspinous dislocation. What had appeared to be a doubling up of the humerus was due to the pulling up and back of the humerus, and to the prominence of the contracted deltoid muscle. The humerus lay almost at right angles to the body, the elbow being greatly displaced outwards. The head of the humerus lay on the dorsum of the scapula just below the middle of the spine. Mr. Miller, who saw it, tried to reduce it by the ordinary method—viz., manipulating the head into the subglenoid position, and then up into the glenoid cavity. This failed, so he put his heel into the axilla, and, using it as a fulcrum, with scarcely any force at all elevated the head of the humerus directly forwards, when it easily slipped into position and remained there. On post-mortem examination there was found to be considerable cerebral hæmorrhage, causing death. On reflecting the skin from the right shoulder, there was a considerable quantity of extravasated blood in the cellular tissue of the shoulder, and between the skin and the deltoid muscle, and below the posterior part of the deltoid. The greater part of the long head of the triceps was torn from the scapula, the tendon being intact. The supra-spinatus and infra-spinatus were torn from the greater tuberosity. The tendinous portion of the teres minor was still attached to the greater tuberosity, while the fibres of

Digitized by Google

its lower muscular part of attachment were torn. The subscapularis was completely torn from the lesser tuberosity. The whole of the capsular ligament was torn from the humerus, and remained attached to the glenoid cavity. The long head of the biceps was torn out of the bicipital groove. There was no extravasation of blood into the pectoral muscles, but there was some under them in the axillary region. When the shoulder was dissected from the trunk, it was easy to demonstrate why the ordinary subglenoid method of reduction was impossible. The head of the humerus had been dislocated directly backwards and *above* the teres minor muscle, so that when the head was manipulated towards the subglenoid position the teres minor tendon became a band stretching round the neck of the humerus and completely barring its course. The coraco-brachialis was put on the stretch, and, had the teres minor given way, would have become also a band round the neck of the humerus, which would tend to prevent its reduction in a similar manner. The specimen, which Mr. Hardyman dissected for Mr. A. G. Miller, has been presented by him to the Royal College of Surgeons' Museum, Edinburgh.

CASE 4.—On Sept. 28th, M. L——, about seven years of age, came complaining that a vehicle had run over her foot. On examination a mark of bruising was visible on the back of the leg, midway between the lower end of the calf and the ankle joint, the foot having been doubled on itself in an antero-posterior direction. There was also on the dorsum of the foot, in the metatarso-tarsal region, two swellings in the region of that joint. This was not a bruise, and on examination proved to be a dislocation of the first, third, and fourth metatarsals on to the dorsum of the foot. The facets were easily distinguishable. The second and fifth metatarsals were not dislocated; dislocation of the second from its peculiarly strong position would almost seem to be impossible. The third metatarsal bone was inclined also abnormally outwards. There was no crepitus. Mr. Hardyman took a cast of the foot, which shows the features very well. The dislocation was reduced under chloroform, each metatarsal separately, by means of pressure with the thumb downwards with extension, without difficulty. The fourth metatarsal, however, required pressure to keep it in position.

CIVIL HOSPITAL, ADEN.

TWO CASES OF PERFORATING WOUND OF THE ABDOMEN, WITH PROTRUSION OF INTESTINE; RECOVERY. URINARY FISTULA; OPERATION; RELIEF.

(Under the care of Surgeon-Major E. COLSON.)

CASE 1. *Penetrating wound of abdomen, with wound of diaphragm and protrusion of intestine and omentum; recovery.*—Hydra A——, Arab, was admitted on June 10th, 1887. He had first of all killed his concubine, and then stabbed himself in the abdomen with a jambier (a crooked Arab dagger). He was brought a distance of six miles to the hospital. On admission there was a wound of about two inches in length in the left hypochondriac region, which had penetrated the abdomen and also extended into the muscular attachments of the diaphragm, and from which about six inches of intestine with omentum protruded. The wound was enlarged downwards, and the intestines in the neighbourhood carefully inspected. They were found to be unwounded, and the abdominal cavity was carefully washed out with carbolic lotion, the mass returned, and the wound fastened with deep sutures and dressed with iodoform. The man made an excellent recovery, although convalescence was somewhat retarded, owing to suppuration occurring in the wound itself, but which evidently had no connexion with the abdominal cavity. He was discharged on July 16th, 1887, for his trial, when he was sentenced to death.

Remarks by Mr. COLSON.—He again came under my care, but this time in my capacity as superintendent of the gaol, in which it was my unhappy duty, having saved his life, to make the necessary arrangements for taking it on the gallows.

CASE 2. *Lacerated and penetrating wound of abdomen; protrusion of intestine and omentum; removal of foreign bodies; recovery.*—Hasir S ——, Arab, aged fourteen years, was admitted into the Civil Hospital on Aug. 20th, 1887. He had fallen from a tree, and in the fall had struck with the abdomen the broken end of a branch lower down, which had penetrated the walls, from which the intestine protruded. He was carried into Aden in this condition nearly twenty miles. On admission, there was found to be a lacerated wound of the abdominal wall in the right hypochondriac region about three inches in length, from which about six inches of unwounded intestine with omentum were protruding. In the protruding mass was entangled a good deal of the green spiculæ which constituted the foliage of the tree from which he had fallen. These were all carefully picked out, the omentum (which was much bruised and in doubtful condition) was ligatured with silk in three places and removed, the abdominal cavity well washed out with carbolic lotion, and the protruding mass returned. The wound was fastened with deep sutures and dressed with iodoform. For the first two days some anxiety was felt about the boy, as symptoms of peritonitis showed themselves. These, however, disappeared, and he made an excellent recovery, and was discharged on Sept. 15th, 1887. His convalescence was somewhat prolonged, owing to the wound healing by granulation.

CASE 3. *Urinary Fistula, associated with almost complete closure of anterior portion of urethra; operation; relief.*—Mohamed A——, an Arab, from Sanáa, the capital of Turkish Arabia, came to the Civil Hospital for treatment. About a year ago he fell from a tree, and alighted astride on a branch ten feet below. After this accident he was unable to pass his urine through the urethra, but through sinuses situated in the scrotum. On admission (July 30th, 1887) he was found to be a healthy young man, and well nourished. The urethra was quite impervious at a point a little behind the scrotum. No urine could be passed through the urethra, but was voided by two sinuses opening through the scrotum. He was placed under chloroform, and Wheelhouse's operation was attempted. The urethra was found to be quite impervious, and converted practically into a fibrous cord. The operation was discontinued, with a view to observing afterwards whether the urine passed through the wound, and whether any passage was apparent. Three days after he was again placed under chloroform, and the wound—which had commenced to heal, and through which the urine had been freely passed—was carefully inspected. No urethral opening could be detected, and a straight bistoury was pushed in towards the prostate according to Cock's method, and after considerable difficulty a large bullet probe was passed into the bladder. This was allowed to remain *in situ* for some hours, but had to be removed owing to the pain it caused. Almost immediately after this second operation urine began to be passed, not only through the wound, but also the penile urethra. The wound gradually closed, and the urine was entirely passed per urethram, in a stream equal to No. 4 catheter. The urethra still continued quite impervious to a catheter beyond a certain point. The man left on Sept. 12th, well satisfied with the result.

Remarks by Mr. COLSON.—The result of this operation, so far as it goes, is fairly satisfactory. The membranous urethra was practically obliterated, and it was a lost hope to again repair the natural canal. What I was successful in doing was to make an artificial passage in the perineum, which opened into the penile and sound portion of the urethra, and which obviated the former distressing condition.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Cartilaginous Tumour of Neck.—Spina Bifida Occulta.—Addison's Disease.—Experimental Tuberculosis and Struma.—Experimental Hæmorrhagic Infarction of Liver.—Lipomatous Fibro-sarcoma of Spinal Cord.

AN ordinary meeting of this Society was held on Tuesday last, Sir James Paget, Bart., F.R.S., President, in the chair.

Mr. F. TREVES showed a specimen of Congenital Cartilaginous Tumour of Neck, taken from the left side of the neck of a girl aged three. The tumour had the appearance of a foreign body, and raised the skin a quarter of an inch. It had existed since birth. The mass was removed, and found to be a curiously shaped mass of cartilage. It was situate over the sternal end of the sterno-mastoid muscle. It was clear that the mass was in the line of the fourth branchial cleft, and a persistent remain akin to the commoner sinus or fistula. A tag of skin over the same situation was another remnant. The present specimen showed no fistula or tag of skin. Fragments of bone may be found lying

Digitized by Google

about this region. In most cases the cartilages are associated with a skin tag or fistula. A fibrous cord extended deeply inwards from the cartilage. The case was unique in the size of the cartilage and in the absence of skin tag or fistula. The specimen of cartilaginous growth published in the *British Medical Journal* was probably not of the same nature, but really a growth in the sterno-mastoid muscle.—Mr. BLAND SUTTON said that he had seen a young woman in whom there was a large mass on each side of the neck about the sterno-mastoid muscle, resembling, and probably representing, a supernumerary auricle. He said Mr. Birkett had described a very similar case in the ninth volume of the Pathological Transactions.—In reply, Mr. TREVES said that he was not aware that Lannelongue's work contained a case of precisely the same nature.

Mr. BLAND SUTTON described a Fœtus with Spina Bifida Occulta associated with several curious Abnormalities. Externally, the fœtus presented a lateral curvature of the spine, talipes equino-varus of the left foot, and atresia ani. On dissection the following abnormalities were found: imperforate pharynx, communication between the trachea and œsophagus; fibrous degeneration of the vermiform appendix; abnormal shortness of the cæcum; absence of the anus, the rectum ending as a cul-de-sac in the prostate, and single kidney. On dissecting the spine, defects were found in the arches of the lumbo-sacral portion, and the central canal of the cord was dilated opposite this point. The spinal cord, which at birth should terminate opposite the second lumbar vertebra, in this fœtus extended to the tip of the coccyx, and ended in a small fatty tumour. On closely examining the spine, a supernumerary half-vertebra was found between the eleventh and twelfth dorsal vertebræ, and a supernumerary half-vertebra of larger size between the twelfth dorsal and first lumbar vertebræ on the right side, thus explaining the tilting of the column to the left. On examining the last lumbar and upper sacral vertebræ a curious fact came to light. Normally the laminæ and spinous processes of a vertebra are formed from two centres of ossification, one for each side, but in these vertebræ it was found that the lamina of each side was composed of two pieces, one representing the pedicles and articular processes, the other the lamina and spine. The bearing of this variation on Neugebauer's view regarding spondylolisthesis was mentioned. The association of malformations of the intestines with syringo-myelocele is something more than casual, and Recklinghausen has described cases of this nature in which gross lesions of bowel accompanied syringomyelocele and spina bifida occulta. These facts serve as additional evidence to support the view that the spinal cord must be regarded as a modified section of the primitive alimentary canal.—Mr. SHATTOCK had recently dissected a similar specimen showing the congenital, not traumatic, solution of continuity of the fifth lumbar vertebra.—Dr. COUPLAND remarked that Mr. Sutton had broken down the commonly accepted distinction between vertebrata and invertebrata.—Mr. BLAND SUTTON, in reply, said that his views would be fully explained in the forthcoming number of *Brain*.

Dr. SAINSBURY read a case of Addison's Disease in which there was a definite traumatic history. The adrenal capsules were unequally affected, indicative of different stages of the disease. The specimens threw light on cases of Addison's disease associated with atrophy of capsules. The specimens indicate the degree to which, subject to fibro-caseous change, atrophy may proceed, and they suggest that some cases described as Addison's disease with simple atrophy may be really examples of the ultimate stage of the fibro-caseous change. It is also suggested that some of the recorded cases of absence of the capsules in association with symptoms of Addison's disease may be examples of extreme atrophy and practical effacement of the organ. The two stages of disease in the capsules are also interesting from their relation with a history of two distinct traumatic records. In cases of apparent atrophy of one or other adrenal, it is thought that the safest method of examination is by cross sections.

Dr. SAMUEL WEST showed specimens of Suprarenal Capsules taken from a lad aged seventeen. Eight months before death the illness began rather suddenly with the usual symptoms. The bronzing was extreme and universal, but less marked in the axillæ and flexures than usual, the legs being most pigmented; the skin over the spines was also coloured more than usual. Congenital and acquired black spots were seen; the latter were watched developing in the skin and mucous membranes. Two or three attacks of twitchings, with some, but not complete, loss of consciousness, were noted at the end of life. The liver was very adherent to the diaphragm, and embedded in fibro-caseous material. General disseminated tuberculosis of the peritoneum was found most marked about the suprarenal capsules, where the fibrous and caseous nodules were larger, and in places calcareous. The pigmentation appeared but one month after the onset of the illness. The local tuberculosis extending from the adrenal disease was very interesting. The microscopical examination was as yet incomplete, but so far no bacilli had been found.—Dr. SAMUEL WILKS insisted on the view that Addison's disease resulted from an essential disease of the suprarenal bodies, and were primarily affected; adventitious affections did not cause the disease. He agreed with the views of Dr. Sainsbury.—Dr. HADDEN contended that so long as the lesion was destructive the kind of morbid process was not an essential condition.

Mr. F. EVE read a paper on an Experimental Inquiry on the Relation of Strumous Gland Disease to Tuberculosis. The author had inoculated rabbits and guinea-pigs from ten cases of strumous glands taken at hazard. No inoculations were performed in the peritoneum, anterior chamber of the eye, or subcutaneous tissue. All the guinea-pigs became affected with visceral tuberculosis, and in four cases the rabbits. In a rabbit, the only one inoculated subcutaneously, a chronic abscess containing tubercle bacilli developed; and a rabbit inoculated from another gland escaped altogether, but this gland had undergone fibrous transformation, and no bacilli could be detected in it. The results of these experiments differed markedly from those of Arloing, who found that while guinea-pigs developed visceral tuberculosis after inoculation with strumous glands, rabbits remained free both when inoculated in the peritoneum and beneath the skin. Arloing, however, only used glands from one subject. He further found that, after tuberculosis from strumous glands had passed through two guinea-pigs, it still did not produce visceral tuberculosis in rabbits. Since the primitive virulence of the micro-organism was not restored by passing it through guinea pigs (which take tuberculosis readily), he concluded that if it is not yet proved that struma and tuberculosis are the work of a distinct virus, yet that of struma, is, perhaps, sufficiently removed from tuberculosis to constitute a distinct variety. The author had repeated these last experiments, and found that rabbits inoculated with strumous gland disease passed once through a guinea-pig developed as acute a tuberculosis as after inoculation with miliary tubercle similarly treated. Specimens were shown for comparison. He could observe no essential difference anatomically between the lesions produced in animals by strumous glands and true tubercle. Tubercle bacilli existed in glands in small numbers, and in abundance in the organs of animals inoculated with glands. After carefully searching two glands and many organs of animals which had been inoculated, he found no evidence that this form of tubercle was the "tuberculose zoogléique" of Malassez and Vignal. The clinically innocent cause of most cases of strumous glands was probably due to the soil in which the organism was implanted, the disease being localised in the glands; perhaps its virulence was slightly attenuated by influences brought to bear in them, but there was nothing to show that, *ab initio*, the virus was a specialised form. The author suggested that the substitution of the term "tuberculous gland disease," "osteitis," &c., for strumous or scrofulous, would remove confusion and tend to a better appreciation of the nature of the disease.—Dr. C. TURNER asked whether the experiments showed that some strumous glands were not tubercular.—In reply, Mr. EVE said that all the cases experimented with proved that the glands were tubercular.

Dr. WOOLDRIDGE showed specimens of Experimental Hæmorrhagic Infarction of the Liver. In human beings such infarctions were of very rare occurrence. The experimental process consisted in injecting a solution of a substance—complex proteid body derived from the thymus and testis—into the jugular vein; the whole vascular system thrombosed in a rabbit, but in a dog complete thrombosis of the portal vein only followed. The animal could also be kept alive for a long time. The liver was filled with hæmorrhagic infarctions if the animal was killed in a few days; but if the animal lived more than a week the clot could not be found. But important structural changes, such as thickening of the capsule and patches of cirrhosis, were found. Sometimes a bleb of blood formed

Digitized by Google

underneath the capsule of the liver. Fatty degeneration and infiltration with cirrhosis could be detected. The capillaries were enormously dilated. A peculiar affection of the gall-bladder, in which a thick layer of blood formed round it, was described. A colourless, tenacious mucus also formed in it and extended into the common duct. This might be a mode of origin of jaundice. Cohnheim and Litten had failed to cause infarctions. In his own specimens there was no thrombosis in the hepatic arteries. The process was neither a simple, inert, nor infective one. The chemical changes in the blood induced a slow clotting. He suggested that many chronic inflammations begin as diseases of the blood, and might not be characterised by progressive changes, but that, once started, their progress might be made by a series of catastrophes which might be arrested at any stage.—Dr. NORMAN MOORE thought that in cirrhosis due to biliary obstruction the idea last mentioned would not hold good. On examination of Dr. Wooldridge's specimen, he had failed to see one characteristic of infarct as ordinarily understood. At St. Bartholomew's Hospital there had never been seen a case of hæmorrhagic infarction of the liver. The embolus and the well-outlined boundary were wanting in the specimens shown, and their absence prevented the acceptance of Dr. Wooldridge's specimens as true infarctions. Dr. COUPLAND did not agree with Dr. N. Moore, and thought that the specimens might justly be called hæmorrhagic infarctions. He hoped for great results from this research.—In reply, Dr. WOOLDRIDGE said that he did not know by what other name to call the result as seen in the specimens handed round.

Dr. CHARLEWOOD TURNER showed a specimen of Tumour of the Spinal Cord. The growth formed an oval swelling in the continuity of the cord, of the size of a large olive. It was composed almost wholly of fat, one-half of the transverse section consisting of simple adipose tissue, the other half of the atrophic remainder of the cord infiltrated with fatty tissue. Microscopical examination of sections of the growth showed that the cord at this part was reduced to a network of nucleated fibrous tissues enclosing areas of fat. In the broader tracts of the fibrous growth were the remains of nervous tissue more or less degenerated. There had been a lipomatous growth developed in the pia mater, ensheathing the cord, which had subsequently invaded the medullary tissue. It was regarded as a lipomatous fibro-sarcoma. There was a gradually increasing weakness for twelve years. It occurred in a young woman whose femur was fractured accidentally. In reply to Mr. Bland Sutton, he said that he had not detected muscular fibres in the tumour.

The following card specimens were shown:—

Dr. ANGEL MONEY: (1) Aortic Aneurysm pressing on Left Bronchus, leading to Bronchiectatic Lung; Erosion of Vertebræ; Empyema; Thickened Pleura. (2) Aortic Aneurysm, perforating Trachea. (3) Hæmatoma of Dura Mater in a Chronic Alcoholic.

Mr. EDWARD BELLAMY: Nævoid Tumour of Scrotum.

Mr. D'ARCY POWER: Submaxillary Gland, with large Salivary Calculus.

Mr. W. G. SPENCER: Stump of Chopart's Amputation.

CLINICAL SOCIETY OF LONDON.

Simple Stricture of Bile Duct.—Peritoneal Surgery for Acute Suppuration and for Tubercular Disease.

AN ordinary meeting of this Society was held on the 28th ult., Dr. W. H. Broadbent, F.R.C.P., President, in the chair.

Dr. SIDNEY PHILLIPS read the notes of a case of Fatal Stricture of the Bile-duct without evidence of Gall-stones. A man aged sixty came under his care at St. Mary's Hospital with obstructive jaundice without obvious cause. The patient had had gout, but never syphilis, and for some years had been a very hard spirit drinker. He had never had colic, vomiting, or any symptom of the passage or impaction of gall-stones. There was no evidence of perihepatitis. While under treatment the gall-bladder became gradually more and more distended, and the jaundice more intense. Much cutaneous irritation, with xanthelasma and purpuric blotches on the skin, were set up, and the patient, after five months, died of exhaustion. At the necropsy there was found a stricture of the common hepatic duct, much resembling a "cartilaginous" stricture of the urethra. There was no ulceration or adhesion of the mucous surface, but the stricture resulted from a tough fibrotic contraction of the outer wall of the duct. The gall-bladder was full of clear fluid; the liver simply enlarged from the obstruction in the duct. Dr. Phillips pointed out that this case, though rare, together with three somewhat similar cases recorded by Dr. Moxon, Dr. G. Johnson, and Mr. T. Holmes, contributed towards establishing the fact that stricture of the bile duct might exist without any symptoms of gall-stones. This was important in the diagnosis of the cause of obstructive jaundice, and might also be of service in the treatment, for, seeing the successful results of cholocystotomy &c., it might be possible to give an exit to the obstructed fluid, or at any rate to postpone one danger, that of rupture of the gall-bladder. Dr. Phillips submitted also that it was very probable not only that stricture was set up without *symptoms* of gall-stones, but also that it might arise from causes entirely unconnected with them. In favour of this, stricture sometimes occurred above the cystic duct, and in a position, therefore, where gall-stones would not pass. The absence of symptoms of gall-stones was also a presumption against their having been present; but the main point which seemed to prove that the stricture was not always due to calculi was that in some cases, as in the one he had recorded, the mucous membrane was not abraded, and the stricture was formed by contraction of the outer fibrous coat of the duct. Sufficient cases had not been reported to decide what causes, if not gall-stones, would produce stricture, but possibly long catarrh might lead to stricture of the bile duct as gleet led to stricture of the urethra.—Dr. COUPLAND briefly related a case of chronic jaundice in which a doubtful diagnosis of stricture of the bile duct was made. The case terminated in recovery after the employment of large doses of iodide of potassium; it was reported in full in the *Medical Times and Gazette* of six years ago.—Dr. F. L. BENHAM related a case in a man aged eighty-six who had biliary colic, but no gall-stones and no carcinoma. The hepatic duct was strictured.—Mr. CHARTERS SYMONDS asked what kind of surgical procedure Dr. Phillips would advocate. He briefly mentioned a case of stricture or simple narrowing of the bile duct in a man which had been under his care twelve years ago. Stricture of these parts could, if detected, be dilated.—Mr. MEREDITH spoke of the possibility of successfully cutting down on the enlarged gall-bladder and examining the various ducts and structures in this region, as he had done himself.—Dr. PHILLIPS, in reply, said there was a real danger of rupture of enlarged gall-bladder. He had seen such a case—in which he had recommended opening the gall-bladder for relief of the obstruction—with Dr. Blake of Harpenden. He had only advocated the relief of tension in cases of biliary obstruction, and doubtless the surgeons would prove themselves fully equal to the cure of the cause of the obstruction; but this was not the matter he had in hand in bringing the case before the Society.

Mr. RICHARD BARWELL read a case of Suppurative Peritonitis; opening, washing, and sponging the peritoneum; recovery. The man, aged forty-two, accustomed to drink a good deal, was admitted into Robertson ward, Charing-cross Hospital, on June 24th, 1887. Six days previously he fell and struck the left lower part of the abdomen, but seemed very little hurt. Five days afterwards, he, in stooping, felt severe pain in the lower part of the abdomen; he vomited and passed a little very dark coloured urine. (Absence or presence of blood cannot be verified.) He went to bed; his abdomen swelled; he passed very little urine; vomited after, and sometimes without, taking food.—24th: On admission he was placed in a warm bath; while in it he passed what may, he thinks, have amounted to a wineglassful of urine. At 2 P.M. Mr. Barwell found him with pinched, anxious countenance, pulse small, hard, and quick, and temperature 100·4°; dry skin; tongue somewhat coated; vomiting; abdomen slightly tender, save in the left iliac region, much swollen, very tympanitic, quite down to the pubes; tapping it produced a peculiar thrill not like that of flatulence. A No. 12 catheter brought away no urine, even though passed far back, but the instrument when withdrawn was full of urine deeply stained with blood.—25th: On three catheterisms 10 oz. of urine had been passed, at first with blood, the last sample free of blood, but slightly albuminous, sp. gr. 1022; temperature 89; pulse 130; abdomen most distended. It being evident that the man had a bad type of acute peritonitis, Mr. Barwell opened the abdomen in the middle line below the umbilicus. A large quantity of gas, not of

Digitized by Google

feculent odour, escaped. No rupture of any viscus was found, but in its lower part the peritoneum contained a quantity of thick pus; there were no adhesions; parts of the intestines were congested, and the membrane was somewhat thickened. Three sponges passed into the lowest part of the cavity were withdrawn covered with tenacious flocculent pus. A smooth-nozzled glass funnel was then deeply introduced, and the part of the cavity washed out with ten pints of distilled water, temperature 99°, bringing away quantities of pus and flocculi. After sponging, a second smaller washing and sponging was directed to the upper part. The abdomen was then sewn close without any drain. The whole operation, including giving the anæsthetic and dressing, lasted an hour.—26th. During the night and day the patient frequently vomited a brown fluid with darker concreta; pulse rather fuller, 110; abdomen scarcely distended, and tender only in immediate neighbourhood of wound. Lies flat, save for a small pillow under the knees; says he is quite well, and wants to go home.—28th. The vomiting slowly decreased during the night; the bowels acted rather copiously four times. The vomiting ceased and all symptoms passed rapidly away. The rest of the history is merely that of rapid convalescence, the man being very importunate in requesting to be discharged. In his remarks, Mr. Barwell, referring to a paper by Mr. Hancock, claimed for Charing-cross Hospital the first conception of the idea of opening the peritoneum for acute peritonitis.[1] He also pointed out that this operation has been performed fourteen times, though the operator has not always known what was the precise nature of the case; and the circumstances have been very various—ulcers or rupture of some part of the intestinal tract, or of an ovarian cyst. He emphasised the impossibility of draining the lower part of the peritoneum through a wound in the front of the abdomen, and advised that no drainage tube should be here inserted immediately after operation, but that, if distension recurred, the lower stitches should be removed and escape permitted. The presence of a tube which cannot in that position act as a drain might be injurious rather than beneficial. In the female, drainage per vaginam would probably be the most valuable treatment.

Mr. LAWFORD KNAGGS (Huddersfield) related the case of a girl aged sixteen years, with Amenorrhœa of four months' standing, who came under treatment for a left-sided abdominal swelling. Some of the fluid was aspirated, and found of sp. gr. 1027, and to contain albumen, paralbumen, large granule cells, and leucocytes. The diagnosis was ovarian cyst. On July 7th, 1886, the abdomen was opened; the peritoneum, mesentery, and intestines were found covered with myriads of pale pink gelatinous-looking tubercles the size of hemp seeds. The ascitic fluid was removed, and the peritoneal cavity washed out with many pints of warm water. General improvement began from the date of the operation. The catamenia reappeared, and she gained 18 lb. in seven months. In March, 1887, she was very well, and went out to service, but the place was hard, and her health declined. Fifteen months after the operation there was no ascites, nor any evidence of the progress of the abdominal disease. She had, however, lost 8 lb. in weight, had morning expectoration, prolonged expiration over the right apex, and cessation of catamenia since July. The interest of the case was its bearing upon the treatment of chronic tubercular peritonitis. Reference was made to a case of laparotomy for intestinal obstruction recorded by the author in THE LANCET, October, 1886. The patient was the subject of tubercular peritonitis. The obstruction was relieved, and the patient, who at the time was greatly emaciated, is now, after two years and a half, a stout and fairly healthy woman. The historical case of Sir Spencer Wells, in which the patient was alive and well twenty-two years after the operation; a similar one, recorded by Dr. John Homan, of Boston, U.S.A., in which the patient was fat and in good health three years after the operation; three recently recorded cases by Dr. Naumann, of which, however, only one recovered; the remarkable experience of Mr. Lawson Tait, who claimed a uniform success so far as the operation was concerned, and a complete cure of the disease in 80 per cent. of all cases of tubercular peritonitis, in which the abdomen was opened, cleaned, and drained—all spoke to the feasibility and suitability of the procedure. Dr. Bantock had pointed out that after abdominal section there was complete immunity from ascites, whereas tapping was always followed by re-

[1] THE LANCET, 1848, Meeting of Medical Society.

accumulation. Why did laparotomy give such satisfactory results? Possibly, as had been suggested by Dr. Cameron of Huddersfield, by removing the toxic chemical products resulting from the life of the bacilli in the tubercles, and accumulated in the ascitic fluid, the absorption of which no doubt favoured the establishment of disease in other organs. The author thought that in certain cases more satisfactory and rapid results might be obtained in this way than by the methods generally employed. He suggested as the most suitable cases those in which the chief clinical symptom was ascites, and where the disease had not attacked or seriously impaired other organs.

Mr. THOMAS KILNER CLARKE read a case of Tubercular Peritonitis cured by washing out the abdominal cavity with a 1 per cent. solution of carbolic acid. On May 10th, 1887, Ann S——, aged thirteen, presented herself among the out-patients. She complained of loss of appetite, distaste of any food, of swelling of the body, of loss of flesh, and increasing weakness. The case being diagnosed as one of tubercular peritonitis, the patient was admitted into the infirmary with a view to operation. On the 11th she was thoroughly examined, and her condition was briefly as follows. She was pale, thin, and with marked hectic flush on each cheek. Temperature 100·2°F.; pulse 120; respiration 20. She walked with difficulty. Both lungs were sound in front, but posteriorly the left lung was dull over its lower half, with absence of fremitus, while the right was suspicious. The abdomen was distended with fluid, but all the other organs seemed healthy. Her previous and family history were both very good. On May 16th Mr. Clarke operated, opening into the peritoneal cavity in the middle line of the abdomen. He found the intestines pushed upwards towards the diaphragm, and both they and the peritoneum studded with little bodies in size and appearance like boiled tapioca grains. The abdominal cavity was well washed out with about two and a half quarts of a 1 per cent. solution of carbolic acid, and without any sponging out of the cavity it was closed in the usual manner. The case did uninterruptedly well. After the first six hours there was no pain, and the patient was comfortable and contented. The temperature reached 101° on the first two evenings after operation, and otherwise was quite satisfactory. The stitches were removed on the seventh day after operation, and on the fifteenth day the patient, having been fitted with a belt, was allowed to get up. On June 5th she was sent to the convalescent home, where she stayed three weeks, gaining nine pounds in weight and improving in health and strength. She showed herself again among the out-patients on July 6th, and was then the very picture of health. She said she was perfectly well. On again examining her, no trace of fluid was found in the abdomen, while both lungs were perfectly sound.

Mr. FREDERICK TREVES said that other inflamed serous cavities, such as the pleura and the joints, were amenable to extensive surgical interference, and the same general principles of treatment were now being applied to the largest serous sac of the body. Already Truc had collected a series of ninety-seven cases of deliberate surgical interference with the peritoneum, and this numerical statement alone sufficed to show the rapidity with which this treatment had spread. As to the claim of priority of the deliberate treatment of peritonitis by washing out the sac, he could only say that he did not gather from a rather verbose correspondence with Mr. Lawson Tait that that gentleman was the first who deliberately performed the operation of abdominal section for the purpose of healing a case of supposed simple peritonitis. The operation had been done in previous cases as the consequence of a mistaken diagnosis, as in Sir Spencer Wells' historical case of tubercular peritonitis. Then, again, Mr. Luke Hancock's writings show that his conception of the treatment of peritonitis was a utopian idea. Just as the poetical outburst of Addison foretold the origin of the telephone, so in an access of surgical exuberance Hancock had predicted this mode of treatment of the peritoneum. In Mr. Barwell's case six days had elapsed before surgical interference. As a rule, such a time would have seen the termination of the career of many cases of acute peritonitis. Moreover, in Mr. Barwell's case but a small part of the peritoneum appeared to have been diseased. The necessity of thorough washing out was made evident by the reflection that the peritoneum was so large a cavity with so many recesses in which fluid might accumulate. He hoped Mr. Barwell would amend his views as to the use of the drainage tube, for if ever there were a case for the use of the drainage tube, surely it was when the peritoneum was

Digitized by Google

the seat of suppurative peritonitis. The principle that underlay the practice was perfect cleanliness. And in some cases he would wash out the stomach if the vomits had been offensive. Next, as to tubercular peritonitis. Kümmell, at the recent Congress of German Surgeons, had collected thirty cases of this disease treated by laparotomy, and others who discussed the paper added six more. Of the whole number six cases ended fatally; twenty-five recovered of the first series of thirty, and only one died of the second series of six. In many cases the operation was done practically by accident on the mistaken diagnosis, as in Dr. L. Knagg's case of encysted peritonitis. Most of the cases occurred in others than young children, and between the ages of fifteen and twenty. It seemed that it was a matter of perfect indifference how the peritoneum was treated so long as it was opened. In young children the treatment was not encouraging. Reference was made to a case of his own in a child fourteen months old; there was so much ascites that the child was almost suffocated by the attendant dyspnœa. At the operation of section peritoneal tubercles were seen. It appeared that the treatment tended to alter the character of the inflammation, and for a time this case did well; but the fatal termination was only averted. Some improvement followed the injection of one pint of a solution of two drachms of tincture of iodine in hot water, at a temperature of 100° F., and for three weeks the child seemed better. At the necropsy general miliary tuberculosis was found. The influence of the ascitic fluid on the growth and nature of tuberculosis was discussed.—Dr. BURNEY YEO, after alluding to the progressive invasion of medical regions by the surgeon, asked for the indications by which the physician might know when the time had arrived for calling in the surgeon. Reference was made to the immense difficulty of diagnosing peritonitis in many cases; for pain and tenderness might be completely absent, and other signs might also be in abeyance.—Dr. GLOVER asked for the evidence of tuberculosis in the cases recorded by Kümmell—Mr. TREVES said in many cases the microscope was used, portions of omentum and other structures being sectionised for examination.—Mr. HOWARD MARSH preferred the employment of a solution of tincture of iodine, 1 per 1000, as the fluid wherewith to wash out the peritoneum. Reference was made to his case of suppuration in the peritoneum published in the last volume of the Royal Medical and Chirurgical Transactions. He related the case of a girl, aged fourteen, with tubercular ascites, treated at first by repeated aspiration, but then unsuccessfully; later he laid the cavity in the peritoneum open, well washed it out with his iodine solution, and with the happiest results. The temperature previously varied from 99° to 103°, but remained normal for ten days after the operation of opening and washing out. Abscesses in the peritoneum, like similar cystic collections elsewhere, should be treated on the same general principle of evacuation, and such cases as the one he just now related would tend to make him an opponent of the aspirator. The recent surgery of the peritoneum in cases of tubercular disease would warrant his saying that cases which before were incurable were now curable by surgical interference. Perforation of the intestine might be prevented by operation, but if the perforation had taken place then there was but little hope of cure; he related a case of perforation of the intestine in six places in illustration of his remarks.—Mr. BENNETT said that the proper time to interfere surgically in cases of tubercular peritonitis could not yet be diagnosed with certainty, and he said this as the result of his experience in two recent cases, in both of which there was apparently every indication for surgical interference; yet in both cases he was not allowed by the parents to operate, and in both cases the children recovered from the peritoneal inflammation. It was difficult to state with certainty in every case whether the diseased products were inside or outside the peritoneum. In one case mentioned the disease was probably retro-peritoneal, and yet if operation had been performed at the commencement of the case he would have had to open the peritoneal sac. Eventually the matter pointed from the iliac fossa, and the abscess being opened recovery speedily followed.—Dr. HERON dilated on the frequency with which patients recovered from strumous—i.e., tubercular—disease of the lymphatic glands, and he also considered that tubercular peritonitis was by no means the fatal disease the surgeons had made it appear.—Mr. GOLDING BIRD instanced the value of mechanical irritation of lupus in the treatment of this disease, and argued that the value of the operative interference with cases of tubercular peritonitis was to be explained on the same principle.—Dr. EDIS argued that cases of peritonitis could exist without any symptoms, and he mentioned two cases of suppurative peritonitis from his own practice, in which there were but few or no indications of this inflammation. He would never drain the peritoneum by way of the vagina.—Mr. MEREDITH considered that it was the mechanical irritation, not the mere washing out, which was of service.—Mr. R. W. PARKER contested the statement that tubercular peritonitis was invariably fatal: on the contrary, recovery was by no means rare. He had been in the habit of contrasting the tolerance of the peritoneum for tubercle with the intolerance of the meninges for the same pathological product. The difference, too, between traumatic and tubercular meningitis was very patent, for recovery was not rare in the former, and was rare in the latter.—Dr. BROADBENT thought that it was too early yet to ask the question when surgical interference should take place. The indications were not yet arrived at. He felt that by surgical measures this form of peritonitis can be cured in some cases more easily and rapidly than by other modes of treatment. He had seen two cases of recovery in children in which at the umbilicus suppuration had occurred. Rapid effusion, too, was not a hopeless sign, for cases might recover after its development. But little allusion had been made by the speakers in the discussion on the pressure of gas in the peritoneal effusion in Mr. Barwell's case, and there were several ways in which to account for its presence.—Mr. BARWELL, in reply, defended his method of treatment.—Dr. L. KNAGGS briefly replied.

MEDICAL SOCIETY OF LONDON.

Double Osteotomy for Ankylosis of the Hips.—Cerebral Tumour.—Cerebellar Ataxy in a Kitten.—Congenital General Elephantoid Condition.—Cross Paralysis.—Charcot's Disease of Hip Joint.

A MEETING of this Society was held on Monday, Oct. 31st, Dr. J. Hughlings Jackson, F.R.S., President, in the chair.

Mr. PEARCE GOULD showed a patient, a young woman, aged twenty-eight, upon whom he had performed the operation of Double Osteotomy of the Femur. When six years old, she was attacked with disease in each hip joint, which slowly ran on to suppuration and dislocation of the head of the femur on to the ilium. When admitted to the London Temperance Hospital, the patient was unable to walk or stand, and each hip was flexed at a right angle to the trunk. On May 12th, Mr. Gould cut down on to each femur, and with a saw divided the bone just above the lesser trochanter—Gant's operation. The wounds healed by first intention. The patient can now stand firmly, and can walk with the help of a stick, and from being a helpless cripple is now able to earn her living as a seamstress.—Mr. C. B. KEETLEY, in cases of ankylosis of both hip joints, recommended excision to be performed on one side and osteotomy on the other.

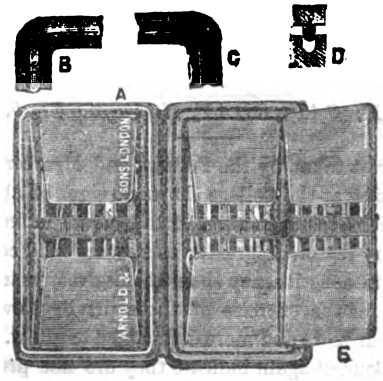
The PRESIDENT showed a man, twenty-one years of age, from whose right cerebral hemisphere Mr. Victor Horsley had removed a tumour more than a year ago. The patient had been subject to fits, beginning in his left thumb and index finger, since May, 1884; some but slight, others more severe, with loss of consciousness. In such seizures along with double optic neuritis tumour was almost certain, but in the absence of neuritis Dr. Jackson was unable to say whether there was tumour or not. In this case there was no neuritis, but it was certain that there was a persistent local "discharging lesion" or "physiological fulminate," or, to use Horsley's term, "epileptogenous focus." Impressed by the ease, certainty, and definiteness with which Horsley and Beevor produced movements in a monkey's thumb by faradising a certain part of its mid-cortex, he suggested that the corresponding part of the cortex in his patient ("the discharging lesion") should be cut out. Mr. Horsley found and removed a tumour, and thus the operation was thoroughly well justified. But, as had been agreed upon before the operation, Mr. Horsley cut out the centre of the "thumb area." The patient was well rid of his tumour, and although he had had eleven fits since the operation, they had all, with one exception, been slight. Before the operation he sometimes had as many as thirteen severe attacks in fifteen days.—Dr. SAVILL referred to a case in which some

Digitized by Google

time after operation fits returned; this, he thought, was explained by cicatricial contraction at the site of removal of the tumour.

Dr. HERRINGHAM showed a Kitten, aged about four months, one of a litter of four, all of whom were affected with a peculiar paralysis. When equilibrium was maintained, the movements of each limb and of the head and neck were normal; but when attempts were made to walk or run, the body swayed over and the cat lost its balance and fell. The diagnosis was failure of development of the cerebellum, based upon a similar case described by Rumpf (*Archiv Psych.*, xvi., 435), and corroborated by post-mortem examination of one of the litter.—Dr. ANDREWS said that under the microscope he found the granular layer of the cerebellum almost absent, and the layer of cortical cells very poorly developed. The spinal cord was normal.

Dr. STEPHEN MACKENZIE exhibited a case of a woman of fifty-nine, with a Congenital General Elephantoid Condition of the extremities, breasts, abdomen, and face. It commenced when she was four years of age with feverish attacks like ague, followed by erythema and desquamation, which were transient, and swelling of the lymphatic glands and subcutaneous tissues, which were permanent. Her father, two brothers, and two sisters were affected. India-rubber bandages had greatly reduced the swelling. The points that he considered particularly worthy of remark were—(1) The condition appeared closely allied to elephantiasis, though the patient had never been out of this country; (2) that it in no way depended on gravitation, though this aggravated the condition; (3) the œdema had not produced anything like the nervous phenomena of myxœdema, showing that "padding of the nerve ends" does not give rise to these symptoms; (4) the heredity of the disease. He thought the condition due to lymphatic obstruction, with consequent overgrowth of tissue.



Dr. SIDNEY PHILLIPS showed a case of cross paralysis in a man aged nineteen, who had a blow on his abdomen. Twenty-six days afterwards the right arm and leg, right side of the face, and left external rectus, became suddenly paralysed with partial anæsthesia. Dr. Phillips thought the coincident paralyses suggested one lesion probably situated on the under surface of the left side of the pons or left crus, and pressing on the sixth nerve. There was nothing to support thrombosis or embolism, and no albuminuria; he considered the symptoms due either to a hæmorrhage or to deposit of callus after fracture of the base of the skull.—Dr. HUGHLINGS JACKSON thought the case one of ordinary hemiplegia, with accidental paralysis of the sixth nerve.—Dr. STEPHEN MACKENZIE thought the absence of lesion of the third nerve excluded the crus as the seat of mischief.—Dr. SAVILL suggested hysteria as a cause.

Mr. HERBERT ALLINGHAM brought forward a case of Dislocation of the Right Hip Joint from Charcot's Disease, associated with lightning pains in the legs, Argyll-Robertson pupils, and loss of patellar reflex and of sexual power.—Dr. ANGEL MONEY had noticed an increase of the knee jerk in many cases of rheumatoid arthritis and synovitis. In cases of extreme emaciation from cancer or typhoid fever this reflex was commonly exaggerated; muscular atrophy, therefore, would not explain its absence.

New Inventions.

IMPROVEMENT IN CASES FOR INSTRUMENTS, ETC.

MESSRS. ARNOLD AND SONS of West Smithfield have patented an invention in the construction of cases with the view of rendering them practically impervious to water and damp. The frames (A) are made preferably of metal, one side of the frame being formed with a groove all round, and the other with a projecting tongue, which, when the two frames are brought into contact, fits into the groove of the frame opposite. The frames may be covered with leather, porpoise hide, or other material, according to the use for which the case is intended, whether to hold surgical instruments—for which purpose the invention is particularly applicable—or other things. For the cases or frames of bags, the arrangement of the frames would be the same, with one side hinged. The inventors prefer fastening the top and the bottom together in the cases, by a leather or other suitable loose

connexion. As applied to instrument, toilet, or dressing and other cases of wood, the groove and tongue may be made in the wood frame, or a metal frame may be fitted to the wood. (See sections B C D.)

NEW FORM OF SUSPENDER.

MESSRS. LYNCH AND CO. of Aldersgate-street have sent us an example of a new form of suspender, made at the suggestion of Mr. W. E. Dawson, for use in inflammatory conditions of the testicles, where it is advisable to apply moist applications. The lower part of the net bag is made of mackintosh and prevents the spread of the application to the patient's clothes. It is also accompanied by a form of calico bag for the penis in cases of urethral discharges, absorbent wool being placed in the end of the bag. The suspensory bandage would be improved by the insertion of elastic in the pelvic band.

SHAW'S PATENT HYGIENIC OVER-SOCK.

THIS over-sock is made of chamois leather, fits over the ordinary stocking or sock, and forms a thin and well-fitting covering to the foot, which is not perceptible in the boot or even in the lowest shoe. They are made in all sizes for either adults or children, and well finished. Although of such simple construction, the over-socks will be found most comfortable to those persons who suffer from cold feet, arising either from exposure to damp or from defective circulation. We can speak favourably of these articles from personal experience. They may be obtained from Earle's Fields Works, Grantham.

"IS CANCER CONTAGIOUS?"

To the Editors of THE LANCET.

SIRS,—The case of M. Duploy, to which you allude in your annotation concerning the contagiousness of cancer in your issue of the 8th inst., and a similar one mentioned in the current number of THE LANCET by Mr. Laslett, give ground for the belief in the possibility of cancer being communicated by one individual to another by actual contact. I therefore venture to allude to another case of a like character. In 1883 a patient of mine, aged fifty-three, died with cancer of the uterus, and I have since been informed that in 1886 her husband, aged fifty-seven, had to submit to amputation of the penis for cancer, of which complaint he died a few months ago.

I am, Sirs, your obedient servant,

Tottenham, Nov. 1st, 1887. E. HOOPER MAY, M.D., F.R.C.S.

AT the meeting of the Cambridge Antiquarian Society, held on the 31st ult. at the University Museum of Archæology, the new President, Professor Alexander Macalister, M.D., delivered an inaugural address on taking the chair.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, NOVEMBER 5, 1887.

THE interest taken by the Fellows and Members in their annual meeting at the College shows no signs of abatement, but rather seems to be growing. Both by more perfect organisation, and by reason of greater earnestness and cogency of argument, the constituency show themselves, year by year, better fitted for the exercise of those privileges which the Council appear more and more disinclined to allow. In their report the Council again indicate they are not prepared to give effect to the recommendation, passed at the annual meeting of last year that Members as well as Fellows should be eligible to sit at the Council Board, and should also take part in the election of its members. As this determination on the part of the Council appeared to be final, and as they have forwarded a petition to the Privy Council for a Supplementary Charter, entirely ignoring the wishes of the Fellows and Members, the Associations of Fellows and of Members respectively have petitioned the Privy Council against the granting of this Supplementary Charter. Such was the condition of affairs at the time of the annual meeting, which was held on the 3rd inst. There remained no other course but to emphasise, by further resolutions, their disapproval, and the disappointment which is felt by a very large section of the Fellows and Members at the continued and unwarrantable disregard shown by the Council to the wishes of the constituency of the College at large. After the presentation of the report (which was taken as read) and a few introductory remarks from the President, Mr. TIMOTHY HOLMES moved the first resolution, which was seconded by Dr. RALPH GOODING,—

"That this meeting disapproves of the application for a new Charter which, *first*, does not confer electoral powers upon Members of the College and the right to be eligible to sit in the Council in accordance with the resolution passed at the general meeting held on Nov. 4th, 1886—namely, 'That it would conduce to the welfare of the Royal College of Surgeons, and would tend to promote the interests of medical polity and education—(1) if Members of the College were empowered to take part (separately or conjointly with the Fellows) in the election of members of the Council; (2) if Members of the College were eligible to sit in the Council, provided (*a*) that no Member of the College shall be entitled to vote till he have been such member for a period of ten years; (*b*) that no Member of the College shall be eligible to sit in the Council till he have been such Member for a period of twenty years; and (*c*) that not more than one-fourth of the Council shall consist of Members of the College who are not also Fellows;'—and, *second*, which does not provide that no alteration shall be effected in the constitution or in the relations of the College, or in any of its bye-laws, without the consent of the Fellows and Members convened to discuss such alteration in accordance with a resolution passed at the general meeting held on March 24th, 1884, and reaffirmed at the meeting held on Oct. 29th, 1885."

It is noteworthy that not only was this resolution passed with absolute unanimity, but this year there was not even a solitary dissentient utterance. This must be gratifying to those who have so long maintained the struggle for reform, especially when it is remembered that there were present a large number of independent Fellows, that is, Fellows who are known not to belong to either of the Associations.

This first resolution having been disposed of, Mr. TWEEDY moved "That this meeting respectfully request the Council of the College to transmit a copy of the foregoing resolution to the Lord President of the Council." This was seconded by Dr. DANFORD THOMAS, and carried unanimously. It is to be hoped that the Council will manfully accept the suggestion, and, as Mr. TWEEDY hinted, fight the matter fairly out.

It would appear as if the individual members of the Council of the College are personally opposed to any change in the directions indicated in the resolutions which have been brought forward at the various meetings. We think for many reasons that this is derogatory to their own dignity. There is scarcely another body of gentlemen who, disposing of trust or public funds, would not be glad, we should think, of the opportunity of lessening their responsibility and of securing representatives of all classes for the Council, on the lines laid down in the resolutions. A larger Council would in no way weaken the present status of that body; while the presence in it of a limited number of Members of the College would satisfy the natural desire of general practitioners to be directly represented, and to have some voice, through their representatives, in the disposal of the sums of money which are largely derived through and from them.

IN the various forms of inflammatory and degenerative disease to which the kidney is liable there has been assigned by all the more recent authorities a very considerable share to the Malpighian corpuscles. Since KLEBS drew attention to "glomerular nephritis" it is remarkable how the tubular lesions have gradually taken a secondary place. In the current number of VIRCHOW'S *Archiv* (Bd. cx., Hft. 1) Dr. HANSEMANN, one of Professor VIRCHOW'S assistants, contributes an article on the subject, which tends, if anything, to limit the sphere of the changes in the glomerular tufts. His pathological study is based on the examination of 120 cases of nephritis, arising under very varied conditions. He prefaces his account of the results obtained in these morbid specimens by a statement of the normal histology of the Malpighian body, which departs slightly from the usually accepted teachings. BOWMAN'S capsule, which is continuous with the basement membrane of the convoluted tubule, is composed of a single layer of cells, the nuclei of which may or may not be centrally situated. The tubule is not constricted at its termination, but expands rapidly in a funnel-shaped manner; whilst developmentally the capsule is formed directly from the curvation of a tubule, and in the same way the epithelial layer covering the glomerular loop is formed. The space between the capsular and glomerular epithelium is filled with fluid, which, according to Dr. HANSEMANN, can be seen in hardened specimens to be traversed by a fine filamentous network. He does not agree with DRASCH'S division of the glomeruli into a larger set placed centrally and a smaller-sized set placed peripherally in the kidney, the former being multilobed and furnished with a nucleated epithelial investment, the latter bilobed and with a non-nucleated covering. For although it is evident that these bodies vary much in size, there is no such manifest separation in structure and situa-

Digitized by Google

tion as DRASCH implies. The glomerular investing membrane is, according to HANSEMANN, merely a layer of cells with scanty nuclei, and cannot, as usually stated, be separated into a basement membrane and endothelium. He also declares that connective-tissue elements are very scanty in the glomerular tuft, being mainly limited to the region of the afferent and efferent vessels; whilst he disputes the statement of BABES that these vessels at their points of entrance and exit are dilated in an ampullary manner, or that such degenerative processes as amyloid and sclerotic changes select these positions for their starting points. The pathological portion of Dr. HANSEMANN'S essay deals in turn with certain questions respecting the *rôle* of the Malpighian body in renal disease, and the replies to these questions are based entirely upon his own histological studies. The first is as to whether these structures take part in every affection of the kidney, and if so, are they attacked simultaneously with or before the rest of the organ? He shows that although in many cases of parenchymatous nephritis, as well as of other diseases, the Malpighian corpuscles are involved, yet that cases do occur in which these corpuscles (even in nephritis) may remain unaffected. In a few instances they are so much affected as necessarily to influence the nutrition of the rest of the renal substance; but it is very rare and quite exceptional to find that glomerular lesions are the first to appear. Another point is as to the part played by nuclear proliferation in the glomerular change. This is always more marked in young subjects, in whom the nuclei are normally more abundant. However, there is undoubted evidence of proliferation of epithelia, more especially of that covering the tuft, besides leucocytal infiltration, which is liable to be mistaken for the former. Further, he denies that the pathological changes —e.g., amyloid degeneration—to which the glomerular tufts are liable afford any evidence that their constituent vessels are provided with a special endothelial lining, as LANGHAUS asserts. On the contrary, he finds that the delicate walls of these capillaries are simply composed of epithelium. In disease of the Malpighian bodies, it would seem that very extensive changes in the direction of swelling, proliferation, and shedding of the epithelial lining of the capsule and tuft may take place without any apparent lesion of the vessels. This of course does not apply to amyloid change, which commences in the vessels. Lastly, in speaking of the relation of glomerular lesions to those of the rest of the kidney, he distinctly discards the doctrine of a primary glomerular nephritis. He quotes COHNHEIM to the effect that it is inconceivable that the several vessels and tubules of the kidney should share equally in the work of secretion, and that inflammation should attack simultaneously all the glomeruli or all the tubules. It accords with experience that nephritis does not involve the whole kidney to an equal extent, or both kidneys in the same degree. And there is sufficient evidence adduced to show that there is no relation between the extent of disease in the glomeruli and that in the rest of the kidney; although it necessarily follows that where a Malpighian body is so diseased as to be functionally destroyed the tubule in connexion with it must be more affected than is the tubule connected with a less damaged glomerulus. In amyloid degeneration, there is, besides the malnutrition induced by interference with blood supply, a probability that the tubule connected with the affected glomerulus atrophies from disuse, being no longer required to fulfil its function. The polyuria of amyloid disease will have, then, to be explained in another way,—but Dr. HANSEMANN does not proffer any such alternative.

THE results of the Contagious Diseases Acts in the colonies have already been given at some length in THE LANCET for October 22nd; but, as was observed at the time, it was necessary to omit much that was interesting from Sir H. T. HOLLAND'S Parliamentary Paper and this deficiency may now to some extent be supplied. We have already dealt with Malta, Hong-Kong, the Straits Settlements, Barbadoes, Jamaica, St. Helena, Labuan, and Trinidad, and now proceed to notice the medical details of the more important districts respecting which these are given. The first is Gibraltar, which, as is well known, is almost insular as regards situation; and from the Governor, Sir A. E. HARDINGE, we learn that the garrison comprises, as a rule, 4600 soldiers. It also appears from the report of Surgeon-General FRASER, the principal medical officer, that there has been a decided increase of venereal diseases among the men of the garrison during the last four years—i.e., since the Acts were first practically suspended and then repealed in this country,—this causing a great importation of disease. The following figures show the ratios of venereal disease in the four years preceding and the four years following the suspension of the Acts:—

Act in Force.

	1879.	1880.	1881.	1882.
Strength of garrison ...	4516 ...	4483 ...	4444 ...	4558
Percentage of venereal disease	8·43 ...	17·19 ...	17·30 ...	20·62

Act Abolished.

	1883.	1884.	1885.	1886.
Strength of garrison ...	4737 ...	4712 ...	4353 ...	4307
Percentage of venereal disease	30·61 ...	28·20 ...	36·20 ...	36·49

This fact alone is sufficiently alarming; but to this must be added the additional one that Gibraltar has always been peculiarly situated as regards what are known as alien prostitutes—those who come from Spain on permits of a day or longer; and as the authorities have only a partial control over them, much disease is spread in this way. There are, in all, sixty-five native and sixty-one alien prostitutes. Out of these no less than thirty-five were admitted into the Lock Hospital in a period of three months and a half, and of these thirty-two were aliens. If, then, the examination of these women is abolished, these diseases will rapidly assume an epidemic form, both among them and the soldiers of the garrison. But even this is not the worst, as Sir A. E. HARDINGE points out: "Moreover if the examination in Gibraltar were dispensed with, all the diseased women compelled to leave Spanish brothels would find their way here either on a daily or weekly ticket. The result would be a state and condition of things that I refrain from depicting." Surgeon-General FRASER observes, in conclusion: "Taking into consideration the numerous points of difference which exist in Gibraltar, compared with other Crown colonies, and the importance of maintaining the health of this important garrison in the most favourable

Digitized by Google

state which efforts in this direction can accomplish, I think it does not admit of any reasonable doubt that with this object in view there actually exists a 'special and local necessity' for not only supporting the regulations affecting prostitutes which are already in force, but of strengthening them to a resemblance of what they were before 1883. I would protest most strongly against their abolition, for that would be followed by the most deplorable consequences to the health of the troops, and a considerable increase of expense to the State from increased daily loss of service, as well as from a higher proportion of invaliding from constitutional syphilitic disease which will inevitably follow."

Passing to Ceylon, it appears that the Ordinance there has been in force since 1867, its operations being limited to Kandy (the ancient capital), Colombo, and Galle, at all of which places troops are stationed, and the two latter are the principal seaports. From Kandy Surgeon-Major FITZGERALD writes: "I believe the Act, when properly enforced, to be most beneficial, and that the only objection to it is that it is not, in my opinion, extended over a sufficiently large area to keep women affected with venereal disease out of the reach of the soldiers." Dr. ARCHER, the Brigade Surgeon in charge of troops in Colombo, says, "In my opinion it is most desirable that the Act should continue to be enforced, on account of the great prevalence of venereal disease amongst the troops and the large number of men thereby rendered constantly non-effective. Last weekly sick returns for this station show twenty-eight patients in hospital suffering from these complaints, or very nearly 44 per cent. of the total sick. There can be little doubt that this ratio would be largely increased were the Ordinance abrogated, especially if infected women were not admitted for treatment to the Venereal Hospital." From Galle Surgeon WALLIS reports: "Galle being a small place and thickly inhabited, if the Act were not in force the disease would increase to such an extent that the consequences would be serious both to the military and civil population, whereas at present the few cases that now occur are not of a virulent type, and arise from outside infections." The Executive Council of the colony in giving special reasons why the Ordinance should be continued, conclude as follows: "The inevitable result of repealing the Ordinance would be a large increase of disease among the civil as well as the military population, and probably an increase of crime." The Governor, Sir A. H. GORDON, adds: "I share the opinion of my Executive Council. The circumstances of England and of an island like Ceylon, as regards such legislation, are so widely different that it is difficult to restrain a movement of impatience at the want of power to realise any such difference which appears to characterise the more fanatical supporters of the repeal of these Acts, and indeed too many others, who conclude that whatever may be unsuitable in England is necessarily unfit for existence elsewhere. In the present case the grave physical, moral, and social mischief which will result from the repeal of the Ordinance is patent; while, on the other hand, the circumstances under which the administration of the Contagious Diseases Acts in England has been held to have inflicted hardship and worked injuriously are absolutely non-existent in Ceylon."

It only remains now to see what has been done in the Fiji Islands. Dr. MCGREGOR, the chief medical officer, in a most elaborate report, mentions that the Ordinance was first passed in 1881, since which it has undergone various modifications. It not only provides for the inspection and detention of prostitutes, but also of immigrants arriving in the colony who are suffering from venereal disease. It appears that among the Fijians there was some time previously to the passing of the Ordinance very little venereal disease—so little that they were practically free from it,—while several thousand Polynesian immigrants were being introduced every year, a large number of whom were suffering from venereal disease. Nothing could have been more distasteful to the native chiefs than the extension of venereal diseases among their people; and there can be no doubt that such diseases, if once suffered to obtain a firm hold on the population, would greatly diminish the birth-rate and largely add to the death-rate. Hence the passing of the Ordinance, which has done a great deal of good in preventing the spread of venereal diseases. Dr. MCGREGOR states that the Indian women are greatly disposed to prostitution, and have made many efforts to establish houses of ill-fame in various parts of the islands; these efforts have been effectually thwarted in many instances by the Act. He concludes: "Looking, therefore, at the whole question from the purely sanitary point of view, it must be held that the repeal of the Ordinance would be a calamity; and it is highly probable that the result of such repeal would create great political discontent in the minds of the native chiefs, and convert the present somewhat unfriendly feelings of the Fijians towards the Indians into dangerous dislike." The Governor, Sir C. B. H. MITCHELL, adds: "I should regard the withdrawal of any precautionary measures against the spread of contagious diseases among the Fijians—a race which is even now showing signs of decay, in that the birth-rate scarcely seems to equal the death-rate—as a great misfortune. As there is no public feeling either amongst Europeans, Fijians, Indians, or Polynesians against the existence of these precautionary measures, and as their repeal may, and probably will, seal the doom of a fine race over whose welfare the English Government is specially pledged to exercise a watchful supervision, I trust that the repeal of the Contagious Diseases Acts of Great Britain, enacted as they were for the protection of a people living under totally different conditions, moral, social, and economic, from those obtaining in these islands, may not be followed by a direction to me to pass an Ordinance to abolish enactments the continuance of which is, in my humble judgment, imperatively required in the interests of Fiji."

While it is satisfactory to observe that the Acts are still to be maintained in Fiji, and probably in Malta also, it is to be regretted that their repeal should be insisted upon in Gibraltar and Ceylon, where, as we have seen, their effects have been so beneficial, and their repeal would be so greatly dreaded by those most capable of judging the probable effects.

THE LANCET of Oct. 8th contains a paper by Dr. GOWERS on the Value to the Medical Practitioner and the Medical Student of a Knowledge of Shorthand. Our present issue contains a letter from the same source describing the particular advantages derived by the student from a knowledge of this art, and advising the formation of shorthand classes in the medical colleges. In these days enter-

Digitized by Google

prise is increasingly active, and is rapidly pushing the bounds of knowledge beyond what is now known in every department of medicine and the sciences allied to it. There is no fixity in the limits of discovery, and errors even seem to the learner to possess a transferable vitality. The tax on memory and reasoning power is not lightened by their disappearance, but is replaced by the exactions of some substitute fact or theory which claims consideration on the authority of later proof. Whatever, therefore, promises to diminish this exaction deserves to command the attention of learners, and shorthand seems to be one of the conveniences especially fitted to fulfil this function. For the student engaged in the lecture theatre it has, as Dr. GOWERS has said, two principal recommendations. Not only is it in an eminent degree saving of time, enabling the student to understand and appreciate, while he transfers to paper, the utterances of a speaker, and observes his illustrations, but it allows him also to note correctly each essential of a discourse, and to exclude any non-essential padding of rhetoric. Thus, the writer is at the same time in some sort a learner. He leaves the lecture room with a clearer idea of his subject than if he had taken notes in longhand, and he may feel himself to be within a measurable distance of accomplishing the feat of memory attributedto Lord MACAULAY, who, it is said, could redeliver a lecture from beginning to end after having once heard it. It may be claimed as an additional advantage that the opportunity afforded for transcribing the notes thus taken into the ordinary written character implies an exercise of mental revision. This, no doubt, is the case, and if the student can spare time for the double notation so much the better. If he cannot, and can easily read his shorthand notes, his best plan certainly is to rest content with these. We are of opinion that those in his position, as a rule, have little time to spare of an evening for the work of transcribing; but there is doubtless room for some difference of opinion on this point. Clinical teaching is for the student of medicine a matter of the first importance, and the essence of such teaching is to train the faculty of observation. In this department shorthand is particularly useful. During the examination of a case there is much in the necessary exercise of the senses, and in the interruptions of question and answer, to interfere with the taking of notes, which, nevertheless, can hardly be dispensed with. To be able to make a permanent record by means of a few symbols is, therefore, an accomplishment of obvious value. This leads us to remark, in passing, the facility in case-taking which is possessed by practitioners, however busy, who have early attained a mastery of this convenient art. Of this class of men Dr. GOWERS is himself an eminent representative. We have now said enough to show that, at all events as far as prospective benefit is concerned, there is justification for the formation of shorthand classes in medical schools. Nor does there seem to be any reason to dread any serious practical difficulties in the way of such a scheme. Teachers are not far to seek. The course need not be a long one, nor the fees high, while, if (as may reasonably be expected) the number of pupils is considerable, they should quite suffice to repay handsomely the trouble of teaching. It is therefore in every way desirable that an effort should be made to bring within the reach of those attending the various hospitals and colleges throughout the kingdom the evident advantages of that useful system which, it is interesting to recall, had for its earliest founder a member of the medical profession.

Annotations.

"Ne quid nimis."

HONOURS EXAMINATIONS AT THE UNIVERSITY OF LONDON.

WE have received numerous letters from teachers and students complaining of the alterations in the Intermediate M.B. Examination at the University of London. These changes are twofold, and came into operation at the last examination in July. We pointed out at the time that the alterations were announced that they would act injuriously on the candidates, and the letters which we have received unanimously support our contention. There can be no adequate reason for commencing this examination so early in the months of January and July, and having an interim of fifteen days between the written and *vivâ voce* parts of the examination. This arrangement is most inconvenient to the candidates and acts unfairly, and can only have been sanctioned in the interests of the executive. The University appoints assistant examiners to aid in reading the papers in some subjects, and if the number of those selected for this duty are insufficient more should be provided. So far as we can understand, there is absolutely no justification for compelling a candidate, at the time of entering his name for the examination, to choose definitely whether he will take the pass paper, and so forego all claim to honours, or the honours paper, and so risk his chance of a pass. If he were allowed to choose at the examination, with the two papers before him, we should still deem it an unwise innovation, but, at any rate, it would give the candidate a much fairer chance than under the present regulation. Teachers in every school are saying that their best men are afraid to run the risk of electing to be tried for a pass on an honours paper, and we have no doubt that this feeling is widespread, and it is quite intelligible. We question if any labour is saved to the examiners, and, even were it so, the authorities are bound to consider the interests and well-being of the candidates in the first instance. The regulation shows that the Senate has, as we have often pointed out, lost all touch with the medical schools. If the Deans or teachers in those schools had been consulted, a unanimous protest would have been sent in to the Senate, and the authorities would have hesitated to pass these regulations, which seem to us, and to all who are conversant with the examination, to have been made solely for the purpose of lightening the work of the executive staff. We would counsel the Senate to restore as quickly as possible their former regulations. If the number of candidates aspiring to honours requires limitation, a simple regulation that every candidate must gain at least two-thirds marks, or some such proportion, in a subject at the pass, before he can offer himself for honours therein, would do all that is necessary for both examiners and candidates.

VACCINATION IN ITALY.

THE severe visitation of small-pox from which the San Frédiano neighbourhood of Florence has suffered constrains the Società Fiorentina d'Igiene to call loudly for compulsory vaccination. Unlike England, France, and Germany, Italy has no uniform legislation for the prevention of small-pox; the only regulation that the most civilised of her provinces possess against the scourge is this—that children cannot be admitted to school or youths to higher institutions without their having been medically certified as

Digitized by Google

having undergone vaccination. But how about the multitude of children who never have an opportunity of requiring this certification—those, in other words, who never go to any kind of school but that of the streets? for it is precisely in this social stratum that the recent outbreak of small-pox in Florence originated, and to which its ravages were almost exclusively restricted. On April 26th last the late Italian premier, Signor Depretis, in the Sanitary Code for the Italian kingdom which he laid before the Senate, made a special feature of compulsory vaccination; and yet there were found public men who combated that provision on the ground that the school certificate of vaccination was sufficient. The epidemic that raged throughout the autumn in the lower quarters of Florence is his justification; and we are glad to see that the Hygienic Society of the city, at the instance of Dr. Boncinelli, adds the weight of its authority to his proposed enactment. Half-measures in matters so important as the public health have had their day; and nothing short of the legislation that protects England, France, and Germany will be tolerated for such a favourite land of foreign sojourn as the Italian peninsula.

INQUESTS ON FIRES.

THE inquest concerning the deaths of four persons killed by the falling of a wall at the recent extensive fire on the premises of Mr. Whiteley, Westbourne-grove, was concluded last week, and, after a prolonged inquiry and the delivery by the jury of their formal verdict, the following rider was added:—"That the present state of the law in regard to fires is most unsatisfactory, inasmuch as it would have allowed the fire at Mr. Whiteley's premises to have passed without any official inquiry but for the fact that deaths arose therefrom; and, further, the jury consider that provision should be made by law for an official inquiry into the origin and circumstances of all fires." We fully endorse the observations of the jury, and consider that the powers which the coroner formerly possessed of holding inquests in cases of fire where no death occurred should be again restored to him. That he had this power in times past is certain; and, further, his power extended to the inquiry of other felonies, such as burglaries and prison breach. Hawkins, in his "Pleas of the Crown," contends that the power of the coroner in those cases was conferred upon him by statute (Edward I.), and was never expressly taken away from him. Some few years ago an attempt was made to establish the authority of coroners to hold inquests in cases of fire, but the question was settled by the leading case of "Regina *v.* Harford," in which Lord Chief Justice Cockburn, in delivering judgment, said: "We have the authority of three of the greatest writers who have expounded and illustrated the law of England for saying that the office of coroner with reference to felonies is limited to cases of homicide on view of the body." Again, Lord Cockburn stayed the coroner for Manchester, who had commenced an inquisition as to a fire, with this judgment: "As to the importance to the public that coroners should have the jurisdiction, there are two opinions. I express none. Some of the coroners in modern times have exercised this jurisdiction, some have not. If they are to exercise it in this and other felonies after the disuse of it for five or six centuries, let it be given them by the Legislature, and not revived by this Court." The late Sir John Humphreys, coroner for East Middlesex, held an inquest at Hackney in respect of a fire where no life was lost. This he did at the special request of the churchwardens and inhabitants of the district, as fires were of such frequent occurrence. The case turned out to be one of arson, but the magistrates refused to reimburse the coroner for the expenses incurred in the holding of the inquest, on the ground that the said inquest was not legally held. By the Coroners Act, 1887, the only Act granting powers to coroners in these matters (4 Edward I.) is repealed. It will be remembered that very recently Sir Robert Fowler and Mr. Hubbard introduced a Bill into Parliament to enable the City Coroner to hold inquests in cases of fire; but the Bill was lost owing to technical objections. Let us hope the City members will return to the charge and recast their Bill in a wider scope so as to include at least the whole of the metropolis, if not extended generally throughout the kingdom. The metropolitan members, as a body, might do far worse than take up this matter on a comprehensive scale when Parliament again assembles.

STRUCTURE OF MUSCLE.

THE Structure of Muscle, one of the most difficult questions in histological research, is the subject of an essay by Mr. C. F. Marshall of Owens College, who gives the following summary of his researches. In all muscles which have to perform rapid and frequent movements a certain portion of the muscle is differentiated to perform the function of contraction, and this portion takes on the form of a very regular and highly specialised intra-cellular network. This network, by its regular arrangement, gives rise to certain optical effects, which cause the peculiar appearances of striped muscle. The contraction of the striped muscle fibre is probably caused by the active contraction of the longitudinal fibrils of the intra-cellular network; the transverse networks appear to be passively elastic, and by their elastic rebound cause the muscle to rapidly resume its relaxed condition when the longitudinal fibrils have ceased to contract; they are possibly also paths for the nervous impulse. In some cases where muscle has hitherto been described as striped but gives no appearance of the network on treatment with the gold and other methods, the apparent striation is due to optical effects caused by a corrugated outline in the fibre. In muscles which do not perform rapid movements, but whose contraction is comparatively slow and peristaltic in nature, this peculiar network is not developed. In most if not all of the invertebrate unstriped muscle there does not appear to be an intra-cellular network in any form, but in the vertebrate unstriped muscle a network is present in the form of longitudinal fibrils only. This possibly represents a form of network intermediate between the typical irregular intra-cellular network of other cells and the highly modified network of striped muscle. The cardiac muscle-cells contain a network similar to that of ordinary striped muscle.

MEANS OF ISOLATION IN LIVERPOOL.

THE position of Liverpool with regard to the isolation of infectious diseases is at present one of extreme difficulty. There is evidence of a commencing increase of scarlet fever; the history of the city is one that gives much anxiety as to typhus at the beginning of a winter which bids fair to be marked by some real privation; and other diseases needing isolation are always more or less prevalent. In the face of these circumstances, it is a deplorable fact that the Town Council are absolutely without means for the reception of infectious diseases other than small-pox, and that, apart from the workhouse hospitals, to which no non-pauper can be legally sent, there is no proper means for protecting the inhabitants against preventable disease. Indeed, Dr. Dawson, in an interview with the deputy medical officer of health as to the need for dealing promptly with some urgent cases, only learnt that it was admittedly an "awful condition of affairs," but that the actual case in question was merely "one of a series." The truth is that Liverpool is suffering from its long postponement of a pressing matter, and although the Cor-

Digitized by Google

poration have at last determined to deal in part with the emergency, they still remain unprepared. The Netherfield-road hospital has been taken over by them; but it is in the hands of the builders, who are to adapt it to modern hospital requirements. A new hospital near the docks has been decided on, and the designs have been prepared and assented to, but it is not yet built. So, also, the chairman of the Sanitary Committee is now urging the Corporation to provide a new hospital site in the east of Liverpool. There can be no question at all as to the need for further means of isolation, for that which will be available when the two newly acquired hospitals are finally ready for use can never be expected to suffice for dealing with the current fevers of Liverpool. It is a pity, therefore, that the matter is again postponed; for whilst we fully believe that temporary erections, as a rule, tend to hinder the provision of permanent hospitals, yet it is an unquestionable gain to have even a site ready for such emergencies as may arise. We hope that at the next meeting of the Council measures will be taken to remove the great defect which now attaches to Liverpool in the matter of dealing with infectious disease.

CHOLERA EPIDEMIC AT MALTA.

IN a report upon the cholera which has recently prevailed as an epidemic at Malta, the Lieutenant Governor and Chief Secretary to Government, the Hon. W. F. Hely-Hutchinson, states that between Aug. 1st and Sept. 26th, a period of fifty-seven days, there were 421 cases and 261 deaths, or an average of 7·23 cases and 4·57 deaths daily. The former were in the ratio of 2·64 and the latter of 1·67 per 1000 of the population. The disease was much more prevalent and fatal in the villages than in the towns, and attacked the poorest, worst lodged, and worst fed of the population. Only one case occurred among the British troops. "Those who rest their faith on sanitary measures rather than on quarantine may find confirmation of their views in the following facts: That in the fortified towns, now drained and supplied with good water, the epidemic has been far less severe than in the villages, which are all undrained; that of the villages which have been attacked, those which have suffered most severely are those dependent on surface water collected in tanks; that although no sort of quarantine or segregation beyond a prohibition to enter Zabbar and Zeitum has hitherto been imposed on the British garrison, only one case has occurred amongst the troops; and that, although no quarantine measures whatever have been taken in Gozo against Malta, only one case, and that a doubtful one, has in the course of fifty-seven days occurred in the neighbouring island."

POSTURE FOR SLEEP AND POSTURE IN SLEEP.

IT would seem on the first blush of the matter that the posture for—that is, to favour—sleep must be generally the same as that voluntarily or instinctively assumed during sleep; but a little consideration will make it apparent that this is not correct. It may be granted that, supposing a person to be sleeping lightly and uncomfortably, the posture will be changed half-consciously to one of comfort. It would be more correct to say that it is changed in the endeavour to avoid distress or discomfort; but even the fact that sleep is quieter in the new position will not suffice to prove that this is a better one, because the sleep may meanwhile have become deeper. It is, on the whole, impossible to ascertain either by experience or observation which is the posture most conducive to sleep, and attempts to lay down rules for the guidance of bad sleepers are always arbitrary, generally empirical, and rarely of any practical value. Those who think "anæmia of the cerebrum" is the cause of sleep, and those who think that, though not the cause, a diminution in the quantity of blood in the vessels of the encephalon is a necessary concomitant of sleep, prefer, and recommend, that the head should be higher than the feet; while those who adopt the opposite view, and think passive congestion causes or promotes somnolence, would have the feet raised and the head lowered. The confounding of stupor with sleep may, and probably has, something to do with these differences of opinion. Meanwhile a common-sense view of the subject would conclude that, as there is evidently some change in the blood state when the brain falls asleep, the best plan must seem to be to place the body in such position that the flow of blood through the vessels of the head and neck may be especially easy and free. The way to secure this is to allow the head to lie in a posture and on a level that cannot offer any obstacle to the free return of blood through the veins of the neck, and does not tend to make the blood flow specially in any particular direction, but leaves Nature at liberty to act as she will.

THE LIVERPOOL ROYAL INFIRMARY.

LAST week two very interesting ceremonies took place in connexion with the rebuilding of the Liverpool Royal Infirmary. The first was the discovery and raising of the old foundation stone of the building now in course of removal. It was found in the north-west corner, and there was leaded into it a brass plate bearing an inscription that it was laid on July 27th, 1821, by the then President of the institution, the Earl of Derby, in the presence of Thomas Leyland, Esq., mayor, the two bailiffs of the old Corporation, and many others. The raising of the stone was witnessed by the present President, Colonel A. H. Browne, M.P., Mr. Gilmour, chairman of the committee, Dr. Davidson, Mr. Mitchell Banks, and others. In a bottle in a cavity of the stone were discovered coins of the day and a copy of a local newspaper. The second ceremony was the laying of the foundation stone of the new building by Lord Derby, in the presence of the Lord Bishop of the diocese, the Mayor (Sir James Poole), and a large and distinguished company, among them the professors of the Liverpool University College and members of the medical and surgical staff. In opening the proceedings, the Mayor alluded to the coincidences that the foundation stones of the first infirmary, erected in 1749, as well as that of the building now removed were both laid by ancestors of the noble lord who was now asked to perform a similar service. Colonel Browne then presented to Lord Derby a silver trowel. The foundation stone, of polished granite and bearing the inscription, "Foundation stone laid by the Earl of Derby, K.G., 29th October, 1887—Queen Victoria's Jubilee year," was lowered and declared duly laid by his lordship; after which, the Bishop having offered up prayer and pronounced the benediction, Lord Derby said that when he was asked some time ago to lay the first stone of this building, he accepted the invitation with pleasure, for it was a good work, a useful work, a work of beneficence and of public spirit, and one which conferred benefits on the community far out of proportion to the capital expended or the mere direct aid given. It was no paradox to affirm that the greatest gainers by the existence of hospitals are to be found amongst those who never enter their doors. They are schools of medical science, where a young man learning his business can see in a few months more cases of various kinds than he would be likely to see in the private practice of a lifetime, where he can profit by the teaching and experience of the leading men of his profession, where a high standard of professional feeling and honour is maintained, and where greed and quackery, and all those practices by which low practitioners sometimes

Digitized by Google

try to push their way into notice, are discountenanced and put down by the full force of an organised and unanimous opinion. An unhealthy people indicates a decay in the community, and the more we know of former times the more surely we are aware that with the growth of civilisation life becomes on the average not only fuller but longer. Of all men, physicians and surgeons give a larger proportion of their time and knowledge—which is their capital—to the unpaid relief of suffering among the poor. We take that as so much a matter of course that we scarcely give them credit for it, but the fact that we do so is in itself the highest praise.

THE SURGICAL TREATMENT OF PERITONITIS.

THE propriety and value of surgical intervention in the treatment of certain forms of peritonitis formed the main subject discussed at the last meeting of the Clinical Society. The cases which gave rise to the debate belonged to two different categories, and perhaps for that reason the discussion was rather involved. It may therefore be convenient to analyse it on each head. In his successful case of acute suppurative peritonitis, Mr. Barwell was pursuing the practice which was brought before the notice of the Royal Medical and Chirurgical Society by Mr. Treves and Mr. Marsh two years ago, giving rise to an interesting debate on the occasion. For although, as Mr. Barwell said, the priority in conception of this procedure rests with the late Mr. Hancock, the operation itself with the deliberate intent of treating the peritoneal condition was first performed by Mr. Treves. It may now be considered not only a legitimate but a very valuable means of treatment, and one which is sure to become more widely practised. Mr. Barwell's case was also instructive, as the President pointed out, on account of the large accumulation of gas present within the abdominal cavity; which makes it more than likely that the peritonitis had been excited by a perforation of the bowel, perhaps of the vermiform appendix. General peritonitis due to perforation is almost invariably fatal, so that physicians may be justified in having early recourse to the aid of the surgeon, who by incision and drainage can promise a more favourable issue. As to the *technique* of the operation, nothing can be simpler, and it was clearly shown that no better medium for washing out the cavity could be employed than pure water, provided this were supplied in sufficient amount, and the irrigation were as thorough as possible. At the Clinical Society more attention was bestowed upon the subject of tubercular peritonitis, the two cases furnished by Dr. Knaggs and Mr. Clarke of Huddersfield forming the chief topic of the debate. Here we may remark how deep-rooted is the notion that tubercular disease of a serous membrane like the peritoneum is necessarily fatal, and the impression conveyed by Dr. Burney Yeo's questions was certainly to that effect. We may refer all those who still hold to this opinion to a clinical lecture on Tubercular Peritonitis in Children, by Dr. Gee, published in this journal six years ago (THE LANCET, Jan. 1st, 1881), and his statement that "recovery from tubercular peritonitis is common" will be endorsed by physicians who practise in children's diseases. In adults cases of recovery from this disease are less common, but Sir Spencer Wells' celebrated case is a standing refutation of the prevalent pessimistic views which would regard tubercular peritonitis as being as hopeless as cancerous. The debate, however, did good service not only in correcting this impression, but in showing how materially recovery is aided by draining the cavity of its contained fluid. Here, again, a lesson may be learnt from the practice often adopted in the case of children with considerable success—viz., simple paracentesis. Whether irrigation and continuous drainage is superior to paracentesis, which may have to be repeated, experience alone will show; but that the essential thing is to withdraw the fluid so as to allow the affected serous surfaces to come into contact was strikingly brought out in the report which Mr. Treves gave of the recently recorded experience of German surgeons. The measure of success obtained did not seem influenced by the adoption of various methods; the essential point was that the peritoneal sac should be laid open. It would thus appear (as was suggested in the debate) as if the effused fluid were itself a source of danger; but that it is absolutely necessary to "alter the character of the inflammation" by the injection of iodine, carbolic acid, or other irritants is still an open question. Dr. Knaggs and Mr. Clarke are to be congratulated on the result of their bold treatment, which may well be adopted in similar cases uncomplicated by active tubercular disease of the lung or ulceration of intestines. Such cases in the adult are not so very common, and their diagnosis is not always simple; but that the local tubercular process may be quite arrested and the general condition of the patient vastly improved by local drainage (aided, of course, as Mr. Parker pointed out, by general treatment) have been amply shown.

FEVER IN LONDON.

THE number of cases of scarlet fever admitted into the hospitals of the Metropolitan Asylums Board during the week ending October 28th amounted to 268, being seven below the number admitted during the preceding week. Speaking generally, there is no abatement of the epidemic, and this view is confirmed by the experience of the first few days of the present week. On Monday the admissions were sixty-four, and on Wednesday morning the total number of cases of fever in the hospitals was 2561, this being the greatest number that has been under treatment in these hospitals during any period of the epidemic. Of this number 162 were enteric, whilst 25 were cases of other diseases. Huts are still being erected on the vacant ground in connexion with the various hospitals. The cases of small-pox were received from the districts of Limehouse and Whitechapel.

OUR NATIONAL PHYSICAL TRAINING.

IF learning were the sole aim of education, life would shortly become a mere competition between different degrees of intellectual capacity. Such it is and must be in a measure, but such it cannot ever entirely be so long as will and character maintain a ruling influence in the affairs of life. The true purpose of teaching is, therefore, to implant not only a knowledge of facts, but a method of thinking correctly, a balance and soundness of mind, and an aptitude for practically applying what is learnt. All through the world, knowledge and purpose, theory and practice, mind and body, have wrought together wherever the energies of man have come to their highest development and have achieved their greatest success. All methods of education, accordingly, must, in order to attain successful results, aim at producing not merely intelligent but capable men and women. The healthy mind in a sound body is still a primary consideration, and it is in recognition of this principle that we cordially support every endeavour to combine with the mental training of school a due amount of physical exercise. To arrive at this desirable end, however, particular efforts are very necessary in the case of city-bred children, though they may be comparatively needless in rural districts where Nature herself may be said to labour effectively in the cause of recreation. It is, in our belief, advisable not only that children so placed should have the opportunity afforded them of improving their muscular tone, but that they should be directly assisted by some system of training appropriate to the end in view. No elaborate process is needed, but there should be aims

Digitized by Google

direct encouragement, including a duly regulated obligation to take part in the exercises and the giving of a few prizes. For adults, who are "but children of a larger growth"—and we do not exclude women,—there is not the same need of systematic training; but for them also the value of regular muscular exercise is hardly less. Happily, the increasing public interest in diversions of this class, and the multiplied variety in which these may be enjoyed, argue well for the future. We note with satisfaction that the Earl of Meath, speaking at Liverpool on the subject, impressed the duty on the School Board authorities and the Government supporting them of making provision for methodical physical training in schools. The suggestion is a very pertinent one, and will not, we hope, fail to receive that attention which it deserves in influential quarters.

CHOLERA IN SICILY.

AN Italian correspondent writes:—"From Palermo I hear that to-day (October 27th) the Minister of Public Instruction has authorised the reopening of the Palermitan University for the winter session, and that by the same authority all the public schools in the city and province will likewise resume work. This he has done on the representation of the Board of Public Health, which is now perfectly satisfied that for the present year at any rate cholera has disappeared from western Sicily. The only sanitary regulation that still remains in force relates to the cemeteries, which will be closed to the public till after All Souls Day, when multitudes of the friends and relatives of the deceased are accustomed to flock to the graves, and often to linger beside them all night in prayer, and in other demonstrations of grief, sometimes ecstatic in its outbursts. As to the rest of the island, sporadic cases of cholera are reported as occurring now in this commune, now in that, but none of these have been officially certified, and it is more than probable that by the close of the month the permission accorded by the Minister of Public Instruction to Palermo and Trapani will also include Catania, Messina, and others of the cholera-visited centres in the east of the island."

THE TELEPHONE IN MEDICAL TREATMENT.

THE very common use of the telephone in the business world affords a sufficient guarantee that, in spite of occasional difficulties, inconveniences, and failures in its working, there remains a substantial balance of advantage. The facilities which it has introduced into the ordinary course of domestic life have also been considerable, though the time is probably yet far distant when even the majority of households will possess the luxury of a telephone communication. In the emergencies of illness, particularly, there is much to be said in favour of this mode of intercourse. It is, above every other, simple, swift, and safe, and must commend itself alike for the expeditious conduct of practice and the treatment of disease. In the management of joint medical practices which cover a considerable area it is very obviously useful. Of its proved value in cases of special urgency, we need say little. A particular interest, however, attaches at the present time to what is probably its latest application. This is its employment as a part of the system of isolation, so imperative in the management of infectious illnesses. We are informed that one of the effects of the recent scarlatinal outbreak in the metropolis has been to establish in some instances an in-door telephone system, which, without the slightest risk of infection, brings a patient, so to speak, within touch of his friends and relatives. Whether this is to be an unmixed advantage must of course depend upon the discretion of those concerned. Rightly used, it may even prove a boon of some considerable curative influence. A certain gain which it confers is of course the comparative leisure allowed to attendants on the sick. There is no answering bells to find out what is needed, the door of the sick-room is less frequently opened, and fatigue generally, as also the risk of infection, is materially lessened. The value of this form of communication in hospitals is obvious. We would suggest its more general adoption were it not that we fear that in many cases the cost might prove a barrier. It would be easy to speak at greater length upon this topic, but it is hardly necessary when the public already recognise, at least in theory, the position of this useful invention among the amenities of life.

BACTERIOLOGY AND PRACTICAL MEDICINE.

THE following interesting survey of the position of bacteriology with respect to medicine is transcribed from the *Centralbl. für Bacteriologie* (No. 18). It appears as an abstract, by Dr. Bujwid of Warsaw, of papers by Dr. Hoyer in the Polish journal *Gazeta Lekarska*. The author, who was the first to commence working at bacteriology in Warsaw, discusses the changes which medicine has undergone by the study of the parasitic origin of infectious diseases, and arrives at the following results:—All researches hitherto undertaken have aimed at learning the excitants of disease; very many of them have been discovered, and many have been profoundly studied, so that the cause of nearly all infectious diseases has been made known; but bacteriology has hitherto confined itself to these limits. Practical medicine in the more limited sense—prophylaxis excepted—has gained very little therefrom, but it may be hoped that the medicine of the future will play quite a different part, in consequence of the deeper knowledge of the various bacteria and their properties. Many purely empirical drugs will be rejected, and in their stead will be employed those which bear directly upon the morbific agent, or which act by strengthening the resistance of the organism. Unfortunately many questions still remain open. We know for instance, very little of the way in which bacteria influence the physiological life of the organism. We cannot as yet determine why many micro-organisms which are introduced into the body in enormous quantities with water, air, or food do not give rise to derangements, or in what manner the really harmful organisms disappear from the blood or organs of some animals. Of great importance for the practitioner are the facts that similar groups of diseases can be excited by wholly different micro-organisms. Abscesses are produced, for instance, by the action of staphylococcus aureus and albus, streptococcus pyogenes, micrococcus tetragenus, and others. Erysipelas following wounds depends not only on the streptococcus erysipelatis of Fehleisen, but also on other streptococci and micro-organisms. Pneumonia is not only excited by Friedländer's pneumonococcus, but also by other bacteria. Two very similar diseases—cholera asiatica and cholera nostras—arise from two very different kinds of bacteria. There are other facts of still greater importance, such as mixed infections. Rosenbach found many very different bacteria in the same abscess. The same is the case with septic infection of wounds. Similarly, as Wiegandt has observed, a kind of streptococcus is occasionally associated with tubercle bacilli. Dr. Dunin has shown that certain complications of typhus depend on the presence of other bacteria &c. When all these questions are solved, then our system of diseases will also be changed; we shall then no longer group them according to symptoms, but causes. There still remain many such questions unsolved. We do not know, for example, upon what depend the different results of experiments on animals when we inject small or large quantities of bacteria. Lastly, we also know very

Digitized by Google

little of the reason why individuality plays so large a part in the manifestation of disease. Very interesting but unexplained is a research pursued by Wysskowitsch. He found that bacteria which had no effect on healthy animals excited diseases in other animals whose organism was slightly deranged. Thus injections of staphylococcus excited endocarditis in animals whose heart valves were injured. When all the foregoing and many like problems are solved, then it will become more easy to employ bacteriology in practical medicine, and then we shall learn to estimate rightly the great value of this new study.

BELGIAN JUDGES ON THE VALUE OF MEDICAL SERVICES.

BELGIAN judges would seem to entertain a very poor appreciation of the value of a medical man's time and services, if we may judge by a case that has recently been tried at Louvain. A medical man in country practice, having attended a wealthy old bachelor for some five months before he died, sent in his account to the executors, who disputed it as exorbitant, and so the doctor was compelled to endeavour to recover his fees by an action in a court of law. The account amounted to 1175 francs (£47), which comprised thirty-eight consultations with a Brussels physician at 20 fr. (760 fr.); fifty-six day visits at 5 fr. and five night visits at 10 fr. (330 fr.); medicines, 85 fr. The defendants denied that the visits with the physician were consultations, and they offered 2 fr. for each day visit and 3 fr. for each night visit. The court, however, "considering that the patient lived three miles from the doctor, who was obliged to make visits at definite predetermined hours along with a colleague from Brussels, and that night journeys, especially in winter, are troublesome," decided that "day visits might be equitably fixed at 2·50 fr. and night visits at 5 fr."; so that all that was allowed the unfortunate practitioner was 235 fr. for ninety-four day visits, 25 fr. for five night visits, and 85 fr. for medicines (the only item which was not disputed), so that the total was cut down to 345 fr. (£13 16*s.*)—a magnificent remuneration, indeed, for such an attendance! A cab-driver would certainly expect more for a similar number of journeys.

ENTERIC FEVER AT BURNRIGGS.

ALTOGETHER, some thirty cases and four deaths have occurred during the prevalence of enteric fever at Burnriggs; and it is stated that the disease is due to pollution of the drinking-water. It is certainly discreditable to find that so many outbreaks are brought about by conditions the removal of which should form part of the current sanitary work of districts. But we fear that there are in the Carlisle rural district many spots where sanitary reform is needed, for it is locally alleged as a reason for inspection by the Government that fever of some kind is nearly always present. The only satisfactory feature of the story is the abundant private help that is being given to the sufferers and their families.

METHODS OF PRODUCING CHLORINE.

PROFESSOR J. CAMPBELL BROWN recently exhibited at the Society of Chemical Industry in Liverpool a new form of apparatus for producing chlorine when required for disinfecting and other purposes. Balls of hypochlorite of lime and gypsum are treated with hydrochloric acid, the supply of which is regulated by the pressure of gas in the generator. Dr. Hamburger has used for this purpose a large flask filled with hot hydrochloric acid, into which a solution of chlorate of soda is allowed to drop by means of a capillary syphon.

THE PATHOLOGICAL SOCIETY.

As will be seen from the report in another column, the meeting of the Pathological Society last Tuesday was rich in interesting matter. Mr. Treves added one more to the list of examples of tumour formation on the site of the branchial arches, his case presenting some noteworthy features. Mr. Bland Sutton's case of "Spina Bifida Occulta" was particularly suggestive, not only from the confirmation it gave to Neugebauer's view of the production of spondylolisthesis, but even more from the remarkable concurrence of numerous malformations of the gastro-intestinal tract (including atresia both of the pharynx and of the anus), with defect in the spinal cord. Mr. Sutton held that such association told strongly in support of the view, which he has elaborated in detail elsewhere, of the common origin of the cerebro-spinal axis and the alimentary tract. The exhibition of diseased adrenals from two well-marked cases of Addison's disease by Drs. Sainsbury and S. West elicited from Dr. Wilks the emphatic reiteration of his belief that the affection is an "essential disease of the suprarenal bodies," and not the result of an "adventitious product, like tubercle"; and he claimed as supporting this view the fact that in Dr. Sainsbury's case one of the capsules had undergone almost entire atrophy. Mr. Eve reopened the subject of the nature of scrofula, and related inoculation experiments in disproof of the conclusion arrived at by Arloing that there is an essential difference between the scrofulous and tubercular virus. His suggestion that the terms "struma" and "scrofula" should be wholly discarded from the nomenclature has been practically adopted for many years, most pathologists fully concurring in the tubercular nature of so-called scrofulous lesions; if the old terms are retained, they certainly no longer bear their old significance. Cohnheim, Friedländer, and Koch have done much to break down the distinction; and it is six years since at the London Congress the like doctrine was urged by Dr. Grancher, Mr. Treves, and others. Far more novel were the interesting results related by Dr. Wooldridge of the experimental production in dogs of multiple portal thrombosis by the injection into the jugular vein of a small quantity of a proteid substance, which has the remarkable power of causing coagulation within the body. The effect on the liver was to produce areas of hæmorrhage, which were not unlike "hæmorrhagic infarcts" in other organs, although Dr. Norman Moore questioned the appropriateness of the use of that term in connexion with them. The secondary effects included coagulative necrosis of the hepatic cells, fatty degeneration, and cirrhosis. Dr. Wooldridge stated that his inquiry was still in a preliminary stage, but considered that it pointed to the influence of blood stasis in the production of organic lesions, which may come to have a very wide application.

DRINK LEGISLATION IN AUSTRIA.

THE Austrian Government have, it is stated, introduced into the Reichsrath a strong measure for the prevention of drunkenness. The reason alleged is the alarming deterioration in the physique of young men enrolled for military service, owing to the spread of spirit drinking amongst the humbler classes. It will be interesting to see if the provisions of this measure are accepted. They would be difficult to carry in this country, where freedom even to get drunk is still jealously guarded. Spirit shops are to be closed at five on Saturday afternoon, and to remain so till five on Monday morning. Ordinary storekeepers are not to be allowed to sell spirits, the sale of which is to be restricted to public houses, confectioners, and specially licensed stores. Dealers serving spirits to intoxicated persons are to be liable to arrest or fine. No debt for spirits consumed on the premises

Digitized by Google

can be recovered by law if the amount exceeds the value of five litres. The magistrates are empowered to forbid retailers to serve spirits to habitual drunkards for any period up to twelve months. Similar legislation already exists in Galicia. The proposal now is to extend it to all Austria. The preamble of the measure sets forth that it is a direct outcome of the Hygienic Congress. It is a striking illustration of the impotence of our own Parliament that no legislation for the restriction of our enormous drinking habits has any chance of being entertained.

ST. JOHN AMBULANCE ASSOCIATION.

IN the annual report of the English Chapter of the Order of St. John of Jerusalem, a number of instances are given of the valuable "first aid" which has been afforded during the year by men who have gone through a course of instruction in the ambulance classes. Suggestions are offered for the raising of local funds to meet the expenses connected with an extension of the system in the mining districts, where accidents are almost of daily occurrence. Provision is made in the Mines Regulation Bill for stretchers and bandages being kept in readiness. But "to have really efficient ambulances requires not only proper appliances, but also willing workers, and it rests with the men themselves to make the movement thoroughly efficient and successful." There can be no doubt that the instruction which has been given under the auspices of the Society has been in a marked degree useful, and especially in the case of the police and of railway *employés*. The report also gives some details of the work done during the year by the Invalid Transport Corps for the conveyance of sick and injured persons (infectious cases excepted). They rendered valuable aid at the India and Colonial Exhibition and the International Exhibition at Liverpool, and this year they have had a station at the American Exhibition. Briefly, it may be stated that between July 31st, 1886, and July 31st, 1887, 290 invalids have been removed from one place to another by the corps, an increase of 116 over the number conveyed in the previous year. Reference is also made to the services rendered by the corps on the occasions of Her Majesty's Jubilee, the children's Jubilee celebration in Hyde Park, the march past of the Volunteers at Buckingham Palace, the laying of the foundation stone of the Imperial Institute, and the Lord Mayor's Show. The utmost credit is due to the members of the committee for the successful manner in which these works of kindness have been performed.

CHLOROSIS AND HEART DISEASE.

EXCESSIVE anæmia being present, and the heart not being hypertrophied, the diagnosis of the cause of heart murmurs is frequently very difficult. M. Duclos has returned to this battle-field of clinicians, and sums up his conclusions in the following propositions:—IN true chlorosis, no matter the number and site of the cardiac murmurs, the basic murmur is never absent, and is most often systolic. In true chlorosis the carotid murmurs, varied and more or less marked, are always present. In genuine chlorosis the bruits are generally more intense and more extensive than in heart disease, and are markedly out of proportion to the circulatory disturbance; further, the cardio-pulmonary circulation remains free, and any disturbance in it indicates the persistence of a valvular lesion, and generally of the mitral valve. We do not join issue with M. Duclos in the general tone of his arguments, which are sound enough so far as they go; but the most frequent clinical difficulty is not so much the differential diagnosis of severe chlorosis from heart disease, as it is the distinction or discovery of valvular lesion in the presence of less marked anæmia.

VOLUNTARY EARLY CLOSING AND SIR JOHN LUBBOCK'S BILL.

A PAMPHLET published recently by "An Old Bristol Shopkeeper" contains a vigorous protest against Sir John Lubbock's prospective Early Closing Bill, by which 8 P.M. will be fixed as the closing hour for shops in general on every day but Saturday. The author contends that this arrangement would practically cripple the trading opportunities of small dealers, who depend largely upon a late class of customers. He regards as bogus tales the bad effect on health attributed to the present system of shop management, and asserts that what is really ruinous is not the protracted duration of work, but its concentrated intensity, and the mismanagement or waste of leisure intervals in book-reading or exciting amusement, assisted by constitutional delicacy in the individual. He states also that the hard and exacting employer is no true type of his class, as the complaining assistant is not the representative of his; and that shopkeepers are, as a rule, favourably disposed to a voluntary early closing system. We are pleased to see that he is inclined to allow to assistants timely opportunities for physical recreation, and we heartily agree with his general statement that we may easily, but must not, have too much law on the subject. We cannot, however, while fully admitting the shrewd good sense of many of his observations, accept his views as affording a sufficient basis for the settlement of this question. He appears to have suffered but little in his own person from the evils of overwork, and consequently thinks little of them. He does not recognise the fact that the disinclination of shopkeepers to act independently retards very materially the progress of voluntary reform, that some combining stimulus appears to be needed, and that meanwhile assistants, who are comparatively at their employer's mercy, work for excessive periods without option for that employer's advantage, and undoubtedly suffer in consequence, physically and mentally. The case with Sir John Lubbock is not one of capricious law-making, and his measure, when it passes, will, we doubt not, be found to be sufficiently elastic to allow for the satisfactory expansion of trade, while restraining its tyrannical exactions. We agree with "An Old Shopkeeper" that voluntary efforts after improvement must be allowed full justice, but we would also take heed that meanwhile the feverish hurry of trade is not suffered to destroy the health upon which we build our hopes of this and the coming generation.

VACCINATION WITH CALF-LYMPH.

A CORRESPONDENT, writing to the *Echo*, complains that his child was vaccinated at the Animal Vaccine Establishment, and that five weeks afterwards an eruption appeared on the arms and legs. The child was received into St. Thomas's Hospital, where it has subsequently recovered. From inquiries we have made it appears that the child has suffered from an eruption due to bromide of potassium, and this circumstance has been fully explained to the parents, but to this the father makes no reference. The case is illustrative of the kind of efforts which are made by those opposed to vaccination to discredit this operation.

THEATRES AND HOSPITAL SUNDAY.

ACCORDING to a contemporary, the theatres have come to the help of the churches to swell the amount of Hospital Sunday collection in Birmingham. We also noticed that in that liberal town the Jews had arranged to hold a service on the Sunday so as to be in harmony with their Christian fellow-townspeople. Such facts really excite the conviction that great religious instincts are common to classes and creeds that are too apt to regard each other as practically

Digitized by Google

opposed. In the theatres the orchestras combined to provide a suitable musical service, and the Rev. Arthur Mursell lectured. Why should London not in this, as in other matters relating to Hospital Sunday, follow Birmingham?

H.I.H. THE CROWN PRINCE OF GERMANY.

WE learn, from trustworthy authority, that the inflammation of the larynx of His Imperial Highness is less in degree and more limited in extent. The voice is clearer and stronger. The general health of the Crown Prince is excellent. His appetite is good. He sleeps well, and takes walking exercise daily when the weather admits. He leaves Baveno this week for Villa Zgirio, San Remo. We hear also that both Prince William and Prince Henry were much pleased with the improvement in the Crown Prince's voice when they visited him on the occasion of his birthday.

SIR R. RAWLINSON ON SANITATION.

SIR ROBERT RAWLINSON turned to good account his opportunity at the municipal banquet given by the Mayor of Stratford-on-Avon. He reminded his hearers that the town had suffered severely from fever in past times, and that it was believed Shakspeare had died from the insanitary conditions surrounding him; and he pointed out that it behoved the residents of Stratford-on-Avon, to which all the English-speaking world came, to make it perfect in all its sanitary arrangements. In England, he said, local authorities were not coerced by a central government; municipal institutions were the foundations of an Englishman's liberty, but it was the more necessary that they should do their best to perfect them. Sir Robert Rawlinson's words should be taken to heart; it is often said that local government is on its trial, and there are many who are too glad to see in its failures reason for altering our method of administration. It is by the exercise of the powers they possess, and by the improvement of districts under their control, that these authorities can best justify their existence.

THE MOXON MEMORIAL.

A MEETING of the committee of the Moxon Memorial was held at the Royal College of Physicians on Tuesday, Nov. 1st, Sir William Jenner in the chair. The treasurer, Mr. Clement Lucas, stated that the subscriptions amounted to £643 8*s.* 6*d.*, and the expenses of printing, postage, and advertising to £32 11*s.* 8*d.*, leaving for the disposal of the committee a sum of £510 16*s.* 10*d.* It was proposed by Sir Dyce Duckworth, and seconded by Mr. Sydney Turner, that £105 should be devoted to the erection of a suitable memorial of Dr. Moxon at Guy's Hospital. It was proposed by Dr. Pavy, and seconded by Mr. Durham, that the remainder of the sum collected (amounting to upwards of £500) should be offered to the Royal College of Physicians to found a Moxon Medal; and it was further suggested that it appeared most appropriate to found a gold medal, to be conferred every third year upon one distinguished for clinical observation and research, whether in medicine or surgery, similar to the Baly Medal in physiology. These resolutions were carried unanimously. After a vote of thanks to the President, the meeting adjourned.

EPIDEMIOLOGICAL SOCIETY.

THE first meeting of this Society for the session 1887-88 will be held at the rooms of the Medical Society in Chandos-street, Cavendish-square, W., on Wednesday the 9th inst., at 8 P.M., when the President, Dr. Thorne Thorne, will deliver the inaugural address, on the Progress of Sanitary Medicine during the Victorian Era.

SIR WILLIAM GULL.

WE are glad to be able to report continued improvement in the condition of Sir William Gull. His strength is now equal to sitting up for a short time daily.

PARENCHYMATOUS NEPHRITIS IN CHILDHOOD.

AUTHORS are not in accord on the subject of the frequency of chronic parenchymatous nephritis in childhood. Many have maintained that the affection is a rare one, and some hold that it is by no means uncommon. Satisfactory statistics on the question are still a desideratum. Baginsky and Ferreira are two of the most recent authors who believe that the disease is not infrequent. The latter considers that diseases of the skin, especially of an impetiginous or ecthymatous character, and involving an extensive cutaneous area, are frequent causes of this form of Bright's disease. The treatment which has proved of most value was the use of astringents of tannin, perchloride of iron, iodide of starch, and diuretic salines, which agents increase the quantity of urine and diminish the albuminuria. Rectal injections of cold water were also employed with benefit; and inhalations of oxygen should not be forgotten, according to Jaccoud and Ferreira.

ST. THOMAS'S HOSPITAL.

AT the Bacteriological Laboratory at this hospital, under the direction of Mr. Ballance and Mr. Shattock, experimental inquiries are still being conducted. It is proposed to remove the apparatus to a larger and more commodious apartment, but no special licence has been granted for experiments on animals. It is now two years since the formation of this laboratory, and much good work has already been done in connexion with it.

PHTHISIS AND CONTAGION.

IN an article in *La Clinique* on the "Contagiosity of Tuberculosis," by MM. Destrée and Slosse, it is stated that from inquiries and observations made in Dr. Desmeth's wards during the present year it was found that, of fifty patients suffering from tuberculosis, contagion could be regarded as an undoubted etiological factor in twelve, heredity in thirty; no cause could be traced in the remaining eight. The two factors, the authors say, are frequently present, and it is difficult to determine to which of them the preponderating influence is to be ascribed.

ARCHANGEL MEDICAL SOCIETY.

WE do not often hear anything of medical matters on the shores of the White Sea. There is, however, a little band of hard-working practitioners in that inhospitable region, who some twenty years ago formed themselves into a Medical Society, which now comprises twenty-eight medical members, twelve of whom are resident in Archangel itself. In the volume of proceedings which has just been published there is an address by the president, Dr. Kosmovski, on the importance of bacteriology to medical statistics, a paper on a sulphur spring of which the town boasts, and a number of statistics of disease in Archangel during the first half of the present year.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Señor Dr. Don Rafael Ariza y Espijo, founder of the Institute of Operative Therapeutics, Madrid, a distinguished Spanish laryngologist, and author of an important monograph on Laryngeal Tuberculosis.—Dr. Leo Zenkovski, Professor of Botany in Kharkoff.

Digitized by Google

THE LATE DR. PANTALEONI.

IT is proposed to erect a monument in memory of the late Dr. Pantaleoni of Rome in his native town of Macerata, and it has been suggested that some of his many friends in this country may like to subscribe to it. Small subscriptions, we are assured, will suffice, for names more than moneys are desired. Contributions towards the carrying out of the project may be sent to the Marchesa Alessandre Costa, Macerata, Italy.

FOREIGN UNIVERSITY INTELLIGENCE.

Kiel.—Count Ferdinand von Spee, *privat-docent* in Embryology and Physiological Anatomy, has been appointed to the post of Prosector of the Anatomical Institute, in succession to Professor Pansch, who was lately drowned.

Leipsig.—Dr. Freitag has qualified as *privat-docent.*

THE Vaccination Department in Belgium has issued a circular, addressed to those who use the department's lymph, stating that during the great heat of the summer months this year the vaccinations performed with the calf lymph supplied by it had not been as successful as usual, and that this had been observed in Stockholm, Linz, Elberfeld, and other places abroad, as well as in Belgium. The director thinks that the unfavourable conditions are now past, and is confident that the vaccine he is now able to supply is quite as efficacious as usual. He suggests, however, that in future medical men will do well to avoid as far as possible arranging vaccinations for the months of June, July, and August.

MR. WYNNE E. BAXTER, coroner of the Eastern Division of Middlesex and for the county of Sussex, has forwarded a request to the Lord Chancellor to exonerate him from the latter office. The action is an unusual one, and the decision of the Lord Chancellor will be awaited with some curiosity, for while precedents are not wanting where the freeholders of a county have petitioned the Lord Chancellor to remove a coroner from office, there is no case on record where the coroner of his own motion has adopted a similar course.

IN the Chancery Division of the High Court of Justice on the 28th ult., Mr. Justice North refused to grant an application to strike out the claim in an action brought by several governors of the Glamorgan Infirmary against the committee of that institution, relating to the recent election of an honorary ophthalmic surgeon.

WE would draw attention to the three female scholarships to St. Anne's Society, the nomination of which is in the hands of the Council of the Royal Medical Benevolent College. Application must be made to the office of the College, 37, Soho-square, London, not later than Nov. 7th. Particulars will be found in our advertisement columns.

THERE were 103 members present at Charing-cross Hospital when Mr. Bellamy delivered his post-graduate lecture on Abdominal Surgery. As the class now numbers 125, Dr. Mitchell Bruce will be assisted by three of his colleagues to-day (Friday), when he gives his lecture and demonstrations on Diseases of the Heart.

AT the Clerkenwell Police Court on the 2nd inst., an order was made for the removal to a hospital of three children suffering from scarlet fever. The father of the children, it was stated, was a tailor, and, with the consent of his employer, was still engaged in his trade.

SMALL-POX is reported to be prevailing to an alarming extent in Sheffield. The public fever hospital is full of patients and many are waiting to enter. The corporation have established a convalescent hospital, and are making preparations for the erection of a temporary hospital outside the town.

MR. WHARTON JONES, F.R.S., contributes to the *Irish Ecclesiastical Gazette* of Oct. 15th, a brief notice of the beginnings of the School of Physic in the University of Dublin. The article, which is also published separately, will have interest especially for members of the profession in the sister isle.

M. PASTEUR'S health is said to be still in an unsatisfactory condition, so much so as to necessitate confinement to his house.

DR. BERNARD KRAUS, chief editor of the *Allgemeinen Wiener medizinischen Zeitung*, died on the 28th inst., aged fifty-nine.

IN the current number of *Illustrations* appears an excellent portrait of the late Dr. Wilson Fox, accompanied by a biography.

HEALTH OF CALCUTTA.[1]

FROM the annual report of the health officer of Calcutta for 1886—the first drawn up by Dr. W. J. Simpson—it appears that the death-rate for the year was only 26·4, being lower than any recorded for the last ten years except that for 1880, and 3·1 under the average of the decade.[2] But Dr. Simpson very fairly remarks that this low rate is in a great measure "due to the fact that the population of Calcutta is largely an immigrant one, and for the most part at an age when the chances of life are at their best. The census figures show that more than half the population are in the full vigour of manhood and womanhood, and that the majority, when they become seriously ill, leave Calcutta for their homes." The death-rate of females is higher than that of males, being respectively 33·7 and 22·7 per 1000 living. The mortality of infants under one year is 404 per 1000, and it is stated that one-fourth of these deaths occur "within fifteen days of their birth, and nearly 90 per cent. of these are registered as dying from tetanus." A table in the report shows the deaths under one year to have been 498 per 1000 of Mahomedans, 405 of Hindoos, 175 of Christians, and 380 of other classes. "To be placed against this great infant mortality is the fact that at the Eden Hospital, where ordinary sanitary arrangements exist, the mortality from tetanus is *nil.*"

The ratio of deaths above stated (26·4) is that for the town only; in the suburbs it was 40·5 per 1000, being the lowest ratio in the decade, and 9·1 under the average of the last nine years. The months in which the greatest number of deaths occurred in Calcutta were December, November, October, and January, ranging from 1377 to 1077; and the smallest number was 688 in June. Fevers were assigned as the cause of more than one-fourth of the deaths in the town, the ratio being 7·90 per 1000; cholera furnished 4·25 and bowel complaints 2·90 per 1000. In the suburbs the ratios were by fevers 14·2, cholera 7·3, and bowel complaints 6·6 per 1000. There was no great prevalence of cholera during the first nine months, but in October a very severe epidemic began, and lasted till the end of the year. Of 1741 deaths in the town, 942, and of 1845 in the suburbs, 1022, occurred in the last quarter. "The incidence of cholera on European sailors using this port, and who, when on shore, frequent many of the worst parts of the native quarters, often breathing its foul air, and partaking of drinks diluted not always with hydrant water," was very heavy, the death-rate

[1] Report of the Health Officer of the Town of Calcutta for 1886, and Resolution of the Commissioners recorded thereon. (W. J. Simpson, M.D., health officer, Calcutta. 1887).

[2] A subsequent table states the mortality of 1880 at 26·9 and the average at 30·6, instead of 29·5 but no clue is given as to the cause of the difference between Tables V. and X.

Digitized by Google

being as high as 11·1 per 1000. Some details with reference to the parts of the town and suburbs in which the epidemic prevailed are given, with illustrative maps. Only 15 deaths from small-pox occurred during the year. Every precaution was taken to prevent the spread of the disease by vaccinating the unprotected in the neighbourhood and revaccinating a large number of persons who had come in contact with the infected.

Dr. Simpson, in his report, has gone at some length into the subject of the defects in the present system of registration of deaths, the need of new building regulations, the "regulating powers in the Municipal Bill being of such a general character that they admit of nothing practical," the disposal of refuse, the material for filling tanks, the need of systematic inspection of premises, and of systematic inquiry into disease. For the latter purpose it is obvious that an organised sanitary staff is necessary, similar to that which was employed during the prevalence of cholera but subsequently discontinued by the Commissioners on the score of economy. The inspection of food brought to the markets has been carried on successfully, and in October an Adulteration of Food Act was passed, which promises beneficial results. This appears to have been much required, for of seventy-one samples of ghee which were examined thirty-seven were found adulterated. The hydrant water was tested regularly, and found to be of good quality; but it was very different in the case of the tank waters, of which seventy-three were examined, "and all pronounced to be unfit for use of any kind." Notwithstanding all that has been done of late years, for which the Commissioners are entitled to much credit, there is evidently still great need of, and room for, extended sanitary improvement both in the town of Calcutta and the suburbs.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Parish of Lambeth.—Dr. Verdon gives an interesting account, in his annual report for 1886, of the conditions under which mortality has steadily for many years past diminished in the southern parishes of the metropolis, and he points out that the rate for Lambeth last year was 19·2 per 1000. Referring to causes of death, he relates an important circumstance in connexion with St. Thomas's Hospital. A child, having been injured in the Westminster-bridge-road, had to remain for several weeks under treatment in that hospital, when suddenly it was seized with a fatal attack of diphtheria, for which no cause could be ascertained. A month later a boy was taken to the same hospital, and, after partial recovery from an operation he had undergone for hernia, he, too, was attacked with diphtheria, and died. Within a period of eight months seven cases of a like nature received into the hospital for operation or from accident died of diphtheria, and, according to Dr. Verdon, the cause remains a mystery. He, however, is inclined to associate the occurrences with the precipitated filth which at low water is exposed beneath the windows of the hospital; and he presses for some adequate solution of the vexed question of the proper disposal of the metropolitan sewage. Summer diarrhœa was above the average last year as a cause of death, 240 fatal attacks being recorded; and, having regard to the changes which milk so rapidly undergoes, he advises that parents should never feed their children with milk that has not been boiled. We would go further, and urge the same precaution in the case of adults. The current sanitary work of the district shows progress in the removal of conditions favouring nuisance and ill-health. Disinfection is well carried out, and some substantial work was done under the Sale of Food and Drugs Act, penalties and costs having been obtained in twenty-three cases.

St. Luke's.—In this metropolitan district the deaths for 1886 were at the rate of 22·8 per 1000, the birth-rate being 38·3 per 1000. A statement is given as to infectious diseases, and the vaccination officer and inspector of nuisances give the results of the working of their respective departments. Dr. Tarrow points to the need for efficient means of disinfecting and destroying infected articles, and he explains that a house-to-house inspection has been systematically carried out. The report is mainly statistical, and it is interesting for local rather than general purposes.

Wolverhampton Urban District.—Dr. Malet shows in a convincing way the great advantages that have followed on early isolation in the borough infectious hospital of cases of the various specific fevers, and, by comparing the east and west districts of the borough, he is able to show that the east, which uses the hospital most, is the one that has had the greatest immunity from the spread of these fevers, and this although that district presents greater facilities for the extension of an infectious fever than does the west. Diarrhœa was very prevalent in the summer of last year, and Dr. Malet in discussing its cause very wisely sets aside the question of fruit being plentiful as a food. The fact is that fatal diarrhœa is, in most places, mainly prevalent at an age that forbids the notion of fruit being an element of any importance in determining the cause. An air containing emanations from midden-privies or from a soil which has been saturated with sewage and slop refuse is a far more potent cause, and one that needs removal in the interests of more than one preventable disease. The corrected death-rate for 1886 is 21·3 per 1000.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5699 births and 3808 deaths were registered during the week ending October 29th. The annual rate of mortality in these towns, which had risen from 17·5 to 19·8 per 1000 in the preceding three weeks, further increased last week to 21·5. During the first four weeks of the current quarter the death-rate in these towns averaged 19·2 per 1000, and was 1·2 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 13·1 in Leicester, 15·1 in Hull, 15·2 in Halifax, and 15·6 in Plymouth. The rates in the other towns ranged upwards to 25·0 in Manchester, 25·1 in Bolton, 26·8 in Blackburn, and 32·1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 382 and 392 in the preceding two weeks, further rose last week to 464; they included 138 from scarlet fever, 76 from measles, 68 from whooping-cough, 65 from diarrhœa, 50 from "fever" (principally enteric), 45 from diphtheria, and 22 from small-pox. These zymotic deaths caused the lowest death-rates last week in Leicester, Plymouth, and Halifax; and the highest rates in Sheffield, Birkenhead, and Bolton. The greatest mortality from scarlet fever occurred in Manchester, Bristol, Huddersfield, Preston, and Birkenhead; from measles in Bradford, Blackburn, Bolton, and Derby; from whooping-cough in Wolverhampton; and from "fever" in Derby and Bolton. The 45 deaths from diphtheria in the twenty-eight towns included 31 in London, 3 in Liverpool, 3 in Salford, and 2 in Huddersfield. Small-pox caused 19 deaths in Sheffield, 1 in London, 1 in Bristol, and 1 in Birmingham. Ten cases of small-pox were under treatment in the metropolitan hospitals receiving cases of this disease, showing a further increase upon recent weekly numbers; while the number of cases of scarlet fever in the Metropolitan Asylums Board hospitals and in the London Fever Hospital had increased to 2532. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding three weeks from 206 to 370, further rose last week to 485, and exceeded by 108 the corrected average. The causes of 78, or 2·0 per cent., of the 3808 deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Wolverhampton, and in four other smaller towns. The largest proportions of uncertified deaths were recorded in Liverpool, Blackburn, Sheffield, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·3 and 19·1 per 1000 in the preceding two weeks, rose again to 22·2 in the week ending Oct. 29th; this rate exceeded by 0·7 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 15·1 and 17·9 Greenock and Paisley, to 24·3 and 25·9 in Glasgow and Perth. The 554 deaths in the eight towns last week

Digitized by Google

showed an increase of 76 upon the number returned in the preceding week, and included 26 which were referred to whooping-cough, 19 to scarlet fever, 11 to diarrhœa, 6 to "fever" (typhus, enteric, or simple), 5 to measles, 3 to diphtheria, and not one to small-pox; in all, 70 deaths resulted from these principal zymotic diseases, against 79 and 68 in the preceding two weeks. These 70 deaths were equal to an annual rate of 2·8 per 1000, which exceeded by 0·3 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 30 and 16 in the previous two weeks, rose again last week to 26, of which 7 occurred in Glasgow, 6 in Dundee, and 5 in Edinburgh. The deaths from scarlet fever, which had been 23 and 22 in the preceding two weeks, further fell to 19 last week, and included 9 in Glasgow and 4 in Dundee. The 11 fatal cases of diarrhœa included 4 in Glasgow and 4 in Dundee. The 6 deaths referred to "fever," of which 4 occurred in Glasgow, corresponded with the number in the previous week. The fatal cases of measles, which had risen from 2 to 5 in the preceding three weeks, were again 5 last week, and included 2 in Edinburgh and 2 in Dundee. Of the 3 deaths referred to diphtheria, 2 occurred in Glasgow. The deaths attributed to acute diseases of the respiratory organs in the eight towns, which had risen from 87 to 120 in the preceding three weeks, further rose to 124 last week, and exceeded by 22 the number returned in the corresponding week of last year. The causes of 71, or nearly 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 27·3 and 24·1 per 1000 in the preceding two weeks, rose again to 32·1 in the week ending October 29th. During the first four weeks of the current quarter the death-rate in the city averaged 26·9 per 1000, the mean rate during the same period being but 18·3 in London and 19·1 in Edinburgh. The 217 deaths in Dublin last week showed an increase of 54 upon the number in the previous week; they included 11 which were referred to scarlet fever, 11 to diarrhœa, 9 to measles, 7 to "fever" (typhus, enteric, or simple), 4 to whooping-cough, and not one either to small-pox or diphtheria. Thus the deaths resulting from these principal zymotic diseases, which had been 36 and 29 in the preceding two weeks, rose again last week to 42; they were equal to an annual rate of 6·2 per 1000, the rate from the same diseases being but 2·5 in London and 2·2 in Edinburgh. The fatal cases of scarlet fever, which had been 11 and 8 in the previous two weeks, rose again to 11 last week. The 11 deaths from diarrhœa exceeded the number recorded in recent weeks. The fatal cases of measles, which had declined from 13 to 5 in the preceding four weeks, rose again last week to 9; the deaths referred to "fever" and to whooping-cough differed but slightly from recent weekly numbers. The deaths both of infants and of elderly persons showed a considerable increase. Seven inquest cases and 2 deaths from violence were registered; and 64, or more than one-fourth, of the deaths occurred in public institutions. The causes of 31, or more than 14 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Brigade Surgeon Elkington, Grenadier Guards, Chief Medical Officer of the Brigade of Guards, will be placed on the retired list on the 5th instant, under the Age Clause of the Medical Warrant. He will be succeeded as Brigade Surgeon by Surgeon-Major W. R. Lane, of the Scots Guards. Deputy Surgeon-General A. F. Bradshaw replaces Deputy Surgeon-General J. Ferguson in Medical charge at Rawal Pindi.

ADMIRALTY.—The following appointments have been made:—Surgeons John Frederick Bate, John Andrews, and John Eustace Webb, to Plymouth Hospital, for temporary service; Surgeons Edward Ashley Spiller and Edward Henry Meaden, to Haslar Hospital, for temporary service (dated Nov. 1st, 1887); and Mr. John J. M'Nulty, to be Surgeon and Agent at Derkmore.

ARTILLERY VOLUNTEERS.—1st Renfrew and Dumbarton: Surgeon J. W. Taylor is granted the honorary rank of Surgeon-Major (dated Oct. 29th, 1887).

RIFLE VOLUNTEERS.—1st Durham: Surgeon and Honorary Surgeon-Major S. W. Broadbent resigns his commission; also is permitted to retain his rank and to wear the uniform of his Corps on his retirement (dated Oct. 29th, 1887).

THE VOLUNTEER MEDICAL STAFF CORPS.—The London Division: Surgeon and Honorary Surgeon-Major John Hornsey Casson resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement (dated Oct. 29th, 1887).—The Manchester Division: Shepherd McCormick Boyd, Gent., to be Surgeon (Supernumerary, dated Oct. 29th, 1887).

Correspondence.

"Audi alteram partem."

"THE PRESYSTOLIC MURMUR, FALSELY SO CALLED."

To the Editors of THE LANCET.

SIRS,—Having endeavoured to prove the correctness of the late Dr. Barclay's explanation of the causation of the "presystolic"[1] bruit, in a paper in vol. vii. (1876) of the St. Thomas' Hospital Reports, and in a communication to the Clinical Society last year (vol. xx., p. 1), I was interested in reading Dr. Dickinson's views upon the subject lately published in your journal. I venture to offer this contribution to the discussion of the subject because I think that something more may be said in support of Dr. Barclay's views, and because I am unable to agree with Dr. Dickinson in one point of his argument. I think the matter can be most succinctly put from this point of view (1) by showing that the physical conditions of the valvular mechanism are such that there must be in cases of mitral stenosis a ventricular systolic bruit, distinguishable or indistinguishable by auscultation, having all the characters of the "presystolic" bruit and the same relations to associated diastolic and systolic bruits, and (2) by pointing out that Dr. Barclay's view is confirmed by clinical observations which show that the "presystolic" period of the ventricular systole is sufficient for the production of an audible bruit, and too great to allow the supposition that a bruit running up to the first sound could be produced by auricular contraction.

1. However perfectly the healthy valvular curtains, with their thin membranous edges, may perform their function, rigid and resistant mitral flaps cannot be brought into contact by the ventricular contraction without some reflux of blood, more or less, according to circumstances. The sound produced by this unavoidable reflux, if audible, would be of progressive intensity until abruptly arrested by contact of the curtains, the sound of valvular tension at the moment of closure being accentuated from delay of the contact of the curtains to a later and more active period of the systole. With rigidity of the mitral valves, the first sound must be preceded by a regurgitant bruit, audible or inaudible to an auscultation, having these characters of the "presystolic" bruit, which are those of arrested reflux. The consideration of another feature of the physical conditions shows that this "presystolic" regurgitant bruit would have the other clinical characters of the well-recognised murmur—i.e., its rough, harsh sound and attendant tremor, its distinction by this character from a succeeding systolic bruit, and its fusion with a precursory diastolic murmur when occurring in association with them. The loudness and harshness of the bruit produced at the mitral valve by the comparatively weak force of the blood stream entering the ventricle or running back through the open valve before contact of the curtains is due to the flaps themselves being held away from the ventricular walls by shortening of the chordæ tendineæ, or by cohesion at the cusps, and being thrown into vibration by the fluid stream passing between them. These valvular vibrations are transmitted by the chordæ tendineæ to the apex of the ventricle, and thence to the part of the chest wall in contact with it, where they may be perceptible as audible and sensible vibration limited to that region. Sonorous vibrations of the valvular curtains set up by the inflowing blood stream may be continued by "presystolic" reflux through the still patent valve, and the bruits of influx and reflux will then

[1] The term "presystolic" is here used as equivalent to "pre-systolic sound."

Digitized by Google

be fused in a continuous sound like the vibrations of a fiddle-string under the backward and forward movement of the bow. But when the mitral curtains have been brought into contact their vibrations will be arrested or deadened, and the whistling sound of regurgitation through chinks between the closed valves is due to the fluid vibrations of the issuing blood. Hence the difference necessarily existing between a "presystolic" bruit, whether direct or regurgitant, and a systolic bruit of valvular incompetence. The former may be compared to the musical notes produced in a wind instrument by the vibrations of the musician's lips in the mouthpiece, and the latter to the whistling sound produced in it by an inexpert person forcibly blowing into it through firmly compressed lips. It thus appears to me that a consideration of the physical conditions of the valvular mechanism in cases of mitral stenosis shows not only that Dr. Barclay's explanation of the causation of the "presystolic" bruit is that suggested by its most obvious character, but that in every such case there must be some "presystolic" regurgitation which would, if of sufficient duration, produce a bruit having all the clinical features of that bruit.

2. But there are not wanting clinical observations to show that this "presystolic" period of the ventricular systole is of sufficient duration for the production of an audible bruit in such cases. The slowness and deliberation of the heart's action, and the disproportionate lengthening of the interval between the second and succeeding first sound in such cases, when the patients are quiescent, was especially referred to by Dr. Barclay, and is a conservative adaptation of the heart's action to the impediment to its functions. That this is attended by a notable prolongation of the "presystolic" interval of the ventricular contraction appears from the direct evidence of the cardiograph. Tracings taken by Dr. Galabin and by the late Dr. Mahomed from such cases show an unusually long interval between the elevations corresponding with the auricular and ventricular contractions. But that which affords the most conclusive evidence on this point is the occurrence of a bruit at the base of the heart, having the same character and the same relation to the second sound that the "presystolic" bruit has to the first sound. A slight bruit of this kind may be not very uncommonly detected, and has been described by several authors. In a case of congenital disease of the pulmonary valve I have heard a "prediastolic" bruit as distinct and characteristic as a well-marked "presystolic" apex murmur.[2] But the conditions are far less favourable to the production of an audible bruit by reflux during the closure of rigid semilunar valves by the elastic resilience of a tense arterial trunk, than during the closure of a rigid and stenosed mitral valve by the comparatively slow and deliberate contraction of the ventricle commencing from a state of muscular relaxation. Hence the occurrence of a "prediastolic" bruit from thickening of the aortic or pulmonary valves, which can only be regurgitant, implies the proportionately frequent occurrence of a "presystolic" bruit from arrested reflux through a thickened but not wholly incompetent mitral valve.

Dr. Barclay's views thus appear to me to be founded on a basis of physical fact, and to be established by clinical observation. But the alternative view appears to me to be purely hypothetical. There would appear to be no proof that the auricular systole could produce a bruit having the character and rhythm of the "presystolic" bruit, which seems to me a great difficulty. Nor would there appear to be any direct evidence of the occurrence of the auricular systole in such immediate relation with the first sound in these cases, which I think is inconsistent with the indications of the cardiograph. Nor do I think that there are any clinical facts to support that view, which can be shown to be incompatible with the other.

I am, Sirs, yours obediently,

Oct. 24th, 1887. F. CHARLEWOOD TURNER, M.D.

To the Editors of THE LANCET.

SIRS,—I wish to add what little I can in support of the views that were so brilliantly and thoroughly put forward by Dr. Dickinson, because I believe them to be correct; and, if correct, they must prove eventually of some importance in regulating *treatment*, notwithstanding the fact that mitral stenosis can be diagnosed whichever view of the pathology of the murmur be accepted. For, I think, we may take it that every fact in physiology and pathology (morbid physiology as well as morbid anatomy) ultimately becomes of direct value in regulating the treatment of disease. Originally trained in the Edinburgh school, I was an unquestioning believer in the auricular-systolic theory of the production of the so-called presystolic murmur; but a series of cases that have been under my care in the Nottingham General Hospital during the last few years, and which have been followed to the post-mortem room, have compelled me to change my views; and when I read Dr. Dickinson's article I had for some time had a paper on the same subject in preparation,

When a heart is beating from 80 to 100 or more times a minute, the interval of time between the auricular systole and the ventricular systole forms such a small fraction of a second that several causes may make a murmur coincident with the beginning of the ventricular systole appear presystolic. The carotid pulse is sufficiently delayed to make a murmur accompanying the *commencement* of the ventricular systole appear to precede it, especially in a rapidly acting heart. But when the rhythm is ascertained by the finger applied to the præcordia, there is still room for error. In the majority of cases of mitral stenosis, from the time they are first recognised, and in all eventually, the right ventricle becomes dilated and hypertrophied (eccentric hypertrophy). The left ventricle is pushed further and further backwards and to the left, and is very little, and in some cases not at all, in contact with the chest wall. The cardiac impulse is diffused, and is chiefly due to the contraction of the *right* ventricle. Is the systole of the two ventricles quite synchronous in mitral stenosis, and, if not, which precedes the other? The great frequence of reduplication of the second sound shows that the systole of the two ventricles cannot be absolutely synchronous, though the difference may be so slight that it is not easy, or perhaps possible, to detect it by the ear as a reduplication of the first sound, especially as in the great majority of cases the sounds, which are longer than the second sound, would coincide in a great part of their duration. But I am satisfied that in dilatation of the right side reduplication of the first sound is more common than is often taught. I am aware that in reduplication of the second sound the pulmonary is generally said to precede the aortic, and that this precedence and the accentuation are said to be due to the increased vascular tension in the pulmonary circulation. I am not satisfied that the pulmonary does always precede the aortic second sound in reduplication, and although the increased vascular tension accounts satisfactorily for the accentuation, it can only indirectly make the semilunar valves close earlier or later. Even though the walls of the ventricle by their contraction have not succeeded in emptying the cavity, the contraction must have ceased, and the onward flow of blood ceased before the semilunar valves can close. Therefore the period of closure of the semilunar valves depends primarily on the ventricular systole. In mitral stenosis with dilated and hypertrophied right side, there is some reason to think that when the ventricles are contracting asynchronously, as shown by the reduplicated second sounds, and the prolonged, altered, or reduplicated first sounds, the left ventricular systole terminates before the right. The left ventricle, being, if anything, underfilled, has no difficulty in expelling its contents. The right, being overfilled with blood at increased tension, in labouring to empty itself, takes rather a longer time to complete the process. In such a case a murmur accompanying the commencement of the left ventricular systole might appear to precede the cardiac impulse, which was due to the latter part of the delayed systole of the right ventricle. This would not apply so much to the early stage of mitral stenosis, when the dilatation of the right side is not so great, and when the impulse of the left ventricle is fairly defined.

But I think it is reasonable to question whether in coördinating the senses of hearing and touch there may not be some loss of time in appreciating the latter; that is to say, whether the *sound* may not be conducted through the chest wall, stethoscope, and ear, to the brain in an appreciably less time than the movement of the ventricular systole can be communicated through the chest wall to the finger and along the arm to the brain. In a rapidly acting heart, and especially in the murmur in question, we are dealing with very small fractions of time. Another difficulty that has

[2] Clinical Transactions, vol. xx., p. 1.

Digitized by Google

been frequently recognised, but never hitherto satisfactorily explained, is the large proportion of cases in which the so-called presystolic murmur is absent, and the still larger number in which it is only present during the earlier stage. The absence of the presystolic murmur when the stenosis is most advanced, *and while the auricle is still acting well, as shown by the efficient maintenance of the circulation*, is quite inexplicable on the auricular-systolic theory of the causation of the murmur. On the ventricular-systolic theory its frequent absence is more easily explained.

In the first stage of stenosis, when the segments of the mitral valve are still capable of closing without allowing any regurgitation, there is no murmur, but only a prolonged, altered, first sound, due to the thickening of the segments, and possibly to a partial want of synchronism in the sounds produced by the two sides of the heart. In the second stage, while the valve is still capable of closing, but moves slowly and so allows of some reflux at first, the characteristic presystolic murmur mounting up to the first sound is produced. In the last stage, when from increased rigidity or calcification the valve is rendered incapable of closure, only a systolic murmur indicative of regurgitation, and lasting during the whole systole, is produced; and the first sound is absent. A very good example of the latter condition has recently been under my care. The mitral orifice was reduced to a narrow slit, the margins of which were calcified, and so rendered incapable of closing. There was no presystolic murmur or first sound, but the latter was replaced by a loud systolic murmur, quite indistinguishable from that due to regurgitation from dilatation of the mitral orifice.

Before closing, may I point out that considerable hypertrophy, affecting the left side—though to a less degree than the right—is much more common in mitral stenosis than is usually taught. The duration of the disease is, I think, the chief element which rules the amount of hypertrophy. It is in young subjects and in rapidly fatal cases that there is little or no hypertrophy.

I am, Sirs, yours faithfully,

Nottingham, Oct. 20th, 1887. H. HANDFORD.

*** On the above subject we have received numerous other letters, for which we regret we are unable to find space.—ED. L.

THE CONSUMPTION OF ALCOHOL.

To the Editors of THE LANCET.

SIRS,—When I read your notice on Sir William Roberts's observations on the subject of alcohol I thought that the following extracts from a paper by M. Fournier de Flaix might be considered sufficiently important to find a place in your journal.

Of France, M. de Flaix says that "the birth-rate is less and the mortality greater in the departments where the consumption of alcohol is small; that neither crime nor suicide are in proportion to alcoholic consumption. Thus in the Seine-Inférieure the consumption of alcohol is three times that in the Nord; but suicide is only twice as frequent. In the Pas-de-Calais the consumption is twice as great as that of the Nord, whilst suicide is two and a half times less. In the Seine-et-Oise the consumption is one-half less than that of the Seine-Inférieure, but suicide in the former is twice that of the latter." Comparing different nations, he says, "France consumes less alcohol than the United Kingdom; its birth-rate is less, and its mortality, criminality, and suicide rates are greater. Italy consumes very little alcohol; its criminality is appalling (*effrayante*). Spain consumes three times less alcohol than Italy; its criminality is double. Sweden, Denmark, and Norway, with a population of about one-third, consume four times the quantity of alcohol consumed in Italy, and yet the criminality of the former is very small, whilst that of the latter is appalling (*effrayante*). Russia consumes four times the alcohol of France; its birth-rate is almost double. Thus, all the hypotheses are upset: the most vigorous, the richest, and the most moral of the nations are those which consume most alcohol. The prediction that alcohol will destroy civilisation and the human race is not supported by facts. If France, whose vitality is undergoing a crisis, were amongst the nations who consume most alcohol, she would serve as an excellent argument; but the consumption of alcohol by France is moderate, and it has been established already that those parts of France are the most vigorous where the consumption of alcohol is greatest. Alcohol is not, then, a scourge which threatens the European race with the fate of the Oceanic races, inasmuch as the nations who consume most alcohol are the nations whose criminality is least and whose vitality is greatest."

I am, Sirs, your obedient servant,

Eastern Hospitals, Homerton, E., Oct. 29th, 1887. ALEX. COLLIE.

SHORTHAND TEACHING IN MEDICAL SCHOOLS.

To the Editors of THE LANCET.

SIRS,—I have reason to believe that a large number of medical students desire to avail themselves of the help in their work that an acquaintance with shorthand can give them. The desire is certainly a reasonable one on the part of those who have to learn by oral teaching, and whose practical work involves the constant recording of observations. Shorthand enables the student to secure as much as he likes of a lecture, while the limitations of longhand are quickly reached; it enables him to keep up with the lecturer in attention, while longhand is always holding him back; and it enables him to record his observations in one quarter of the time required with longhand, and thus in a given period he can record twice as much, and yet have 50 per cent. more time in which to observe. The last is a very great help in case-taking, and in a competitive examination the student who writes shorthand has a considerable advantage over one who does not. Shorthand can be learned far better and far more quickly from a teacher than by self-instruction. But for students to go to a shorthand class at a distance, almost necessarily in the evening, means a loss of time that is practically prohibitory. I believe that every medical school at the present moment contains enough students desiring to learn shorthand to make it worth while to establish a class, and I would suggest to the authorities of the schools the desirability of ascertaining the extent of the demand, and, if it is considerable, arranging for the means of instruction. The time required for the study is not great. Half-an-hour's work a day will in six weeks enable the student to make use of shorthand in his daily work, and all the time needed for proficiency will be saved at least twice over in a single year. Teachers of shorthand are readily obtained. I shall be glad to give information on this or any other point connected with the subject.

I am, Sirs, yours truly,

Queen Anne-street, Oct. 31st, 1887. W. R. GOWERS.

"PARALYSIS OF THE ABDUCTORS OF THE VOCAL BANDS."

To the Editors of THE LANCET.

SIRS,—Without entering upon numerous other points of controversial nature in Dr. Gordon Holmes's paper on the above subject which has just been published in your columns, I wish to point out one important mistake, and also to state that the list of cases given in the paper is incomplete, and not quite correct in certain particulars.

The mistake referred to concerns the motor innervation of the larynx. The notion that the spinal accessory nerve supplies only the adductors of the vocal cord, but not the posterior crico-arytenoid muscle, is certainly erroneous. Bischoff's and Schech's experiments, which showed that the spinal accessory supplied both the adductors and the abductor, have again been recently confirmed by Professor Horsley. He succeeded, in my presence, in cutting the inner (bulbar) branch of the left spinal accessory of a dog, leaving, as subsequent post-mortem examination showed, the external (spinal) branch of the spinal accessory and the pneumogastric absolutely uninjured. The immediate result of this experiment was complete cessation of all respiratory movements of the left vocal cord, which at once became absolutely fixed in what is commonly called the "cadaveric position." This experiment proves incontrovertibly that the motor fibres not only for the adductors, but also for the abductors, are derived from the spinal accessory.

Concerning Dr. Holmes's tables, I have to say that I have myself published, in greater or lesser detail, not three but eleven cases of bilateral abductor paralysis (Clinical Society's Transactions, vols. xi. and xii.; *Archives of Laryn-*

Digitized by Google

gology, 1881 and 1882; Transactions of the Pathological Society for 1882; *Berliner Klinische Wochenschrift*, 1883; St. Thomas's Hospital Reports, vol. xiii.) Besides, I have repeatedly shown illustrative cases before Medical Societies (see, e.g., *Brit. Med. Journal*, April 4th, 1885, p. 701). To what case of mine Dr. Holmes is referring under the heading "Pressure from Catarrhal Thickening" (No. 42 of his list) I cannot make out. I have certainly not published a case under this or any similar title. The heading "Cancer (post-tracheal)" of Case 49 of his list refers, I suppose, to my case of bilateral abductor paralysis, due to probably malignant disease of the thyroid gland, published in the Pathological Society's Transactions. But I am not certain of this. Apart from this, Dr. Holmes's list, although it goes down to nearly the middle of last year, is incomplete. In the first place, he has left out several of the older reported cases already referred to in my own papers on the subject—such as Weber's, Krishaber's, Sajous', Schuberg's, Duvening's (two),—without stating his reasons for doing so. And, further, he has omitted, of more recent instances apart from Dr. Saundby's case, the following:—Ott's second case (*Prager Med. Wochenschrift*, No. 14, 1884), Young's case (*Brit. Med. Journal*, April 26th, 1884), Dehio's two cases (*St. Petersburger Med. Wochenschrift*, 1884, Nos. 26 to 28), Kothe's two cases (*Berliner Klin. Woch.*, p. 734 *et seq.*, 1884), Mackenzie Johnston's case (*Edinburgh Medical Journal*, June, 1885), Ziegelmeyer's case (*Bericht über die Sommersaison, &c.*, Bruchsal, D. Weber, 1885), Koschlakoff's case (*Russ. Med.*, Nos. 1 and 2, 1885), M'Bride's case (*Edinburgh Medical Journal*, July, 1885), T. Solis Cohen's case (Transactions of the American Laryngological Association, 1886), E. Remak's case (*Berl. Klin. Woch.*, No. 25, 1886), Smyth's case (*Indian Med. Gazette*, October, 1886), Landgraf-Martin's case (*Berl. Klin. Woch.*, No. 8, 1887), Felici's case (*Arch. Italiani di Laryngol.*, fascic. ii., 1887), A. E. Garrod's case (St. Bartholomew's Hospital Reports, vol. xxii., 1886), Beschorner's case (*Monatsschrift für Ohrenheilkunde*, No. 5, 1887), Percy Kidd's case (THE LANCET, July 15th, 1887), Ramon de la Sota's case (*Revista Medica de Sevilla*, t. ix., 1886), Kuessner-Wegener's two cases (*Berlin Thesis*, 1887), and Luc's case (*La France Médicale*, No. 15, 1887). Thus no less than thirty-seven cases which have been reported in detail are wanting to make Dr. Holmes's list of published cases complete to date. Amongst the cases I have quoted above are *not* included many which are doubtful, nor the numerous instances in which paresis or paralysis of the abductors has followed tracheotomy in children or extirpation of the thyroid gland. From my own experience I am led to the conclusion that the bilateral affection is not so rare as is generally believed. Between 1876 and the present date I have seen in my own hospital and private practice, and in that of medical friends who kindly invited me to see their patients, nearly thirty cases.

I am, Sirs, yours obediently,

Wimpole-street, Nov. 1st, 1887. FELIX SEMON, M.D.

"WELL-TO-DO MEMBERS OF FRIENDLY SOCIETIES AND MEDICAL ATTENDANCE."

To the Editors of THE LANCET.

SIRS,—In your issue of Oct. 22nd, under the above heading, you mention you would look with interest to the next meeting of the lodge of the Manchester Unity that had summoned me to attend in reply to a charge that I had wanted a fee from one of the members whom I considered the payment of 1*d.* per week was never intended to include. The meeting was well attended and I received a patient and courteous hearing; all was done in order, and resulted in a vote by a large majority that I should withdraw my resignation; and they subsequently carried a hearty vote of thanks and confidence. Several of the members spoke feelingly, and with gratitude, as to the benefit and attention they had received from me in their illness. The question as to increased payment was referred to a future occasion, and the Secretary expressed his regret that, if I was dissatisfied with the remuneration, I had not, in accordance with their rule, made an application in writing to the lodge for an increase of salary, and then it would have been the duty of the presiding officer to give instructions for the subject to be placed on the agenda at the next general meeting, when the matter would be fully considered, as it would require an alteration of the lodge's bye-rules. I am not so anxious about the increase of my salary as the question of higher payments by the *well-to-do members*.

I am, Sirs, your obedient servant,

Oct. 29th, 1887. FREDK. H. ALDERSON, M.D.

*** As we anticipated, the question in dispute between Dr. Alderson and his lodge—the Albion Lodge of the Manchester Unity of Oddfellows—is not likely to endanger that good feeling which has characterised their relations for twenty years. Though he felt it right to proffer his resignation, he was by a large majority asked to withdraw it, and a hearty vote of confidence was passed. The course suggested by the Secretary is a right one. Any dissatisfaction with the remuneration should be carefully stated, and an application should be made to the presiding officer of the lodge for an increase of salary. The matter would then be placed on the agenda and carefully discussed.—ED. L.

THE CONGRESS OF HYGIENE IN HUNGARY.

(From our Special Correspondent.)

Buda-Pesth, Oct. 14th.

WITH a military band on board, and the ship gaily decked with flags, early on the Monday morning 400 members of the International Congress of Hygiene sailed down the Danube for Buda-Pesth. Some 300 more, for whom room could not be found on board, proceeded to the Hungarian capital by train. The large river steamer, with its saloons, its dining accommodation, and its spacious deck, gave the best opportunities for the exchange of ideas, of news, and of criticisms; and the long journey to Buda-Pesth must have greatly contributed to facilitate mutual understanding between sanitary reformers of all countries. Presburg was the first Hungarian town reached; and here the entire population turned out to welcome the Congress. The broad enbankment was lined with dense crowds of people; from masts, balconies, and the roofs of the houses floated innumerable flags; on the pier the Mayor and municipality awaited to present an address of welcome. It was a brilliant and invigorating sight. In a few minutes, however, the steamer started again, followed far by the re-echoing cry of *élien* (the Hungarian "hurrah")! Though it was close upon 11 o'clock when we reached Buda-Pesth, the Mayor and municipality here also were present to greet the members of the Congress with speeches of suitable brevity. A most elaborate programme had been drawn up for the next three days' proceedings, and the wearied members of the Congress were anxious to snatch a few hours' rest. At 7 o'clock next morning the Congress was to meet, so as to visit the Veterinary School and the School of Physiology before 10 o'clock. Both these institutions were greatly admired, the English members expressing themselves in particularly complimentary terms with respect to the Hungarian Veterinary School. The Chemical Laboratory, constructed in simple Italian Renaissance style, cost, taking the florin at its nominal value, £36,613, and the Physiological Institute £41,133. Here, in the rooms for experiments, 200 students can be easily seated; while, covering a superficial area of 2095 square metres, and costing £43,200, there is the School of Mineralogy, Anthropology, Geology, and Botany; and, finally, a library that cost £27,500. All these buildings form but one group, and are conveniently near each other.

Before further describing the great educational and scientific work accomplished at Buda-Pesth, it should be remarked that in 1780 the town had only 23,000 inhabitants. In 1867, while Hungary was still under the domination of Austria, the population of the capital was 183,360; but since Hungary gained its independence, the progress has been so rapid that the population of the capital is now estimated at 450,000, and since 1867 the State has spent no less than £7,000,000 in public works at Buda-Pesth. At 10 o'clock, according to appointment, the members of the Congress, who filled a long line of tramcars, arrived at the Ulloi-street Clinical Hospital and School, a magnificent and luxurious building, which cost £42,800. The adjoining Anatomical

Digitized by Google

Institute by itself cost £32,000. These structures were much admired. Though there was scarcely time to make a technical examination, this much at least can be said—namely, that the drainage seemed in proper order, and was infinitely superior to what is generally seen on the Continent. At 11 o'clock the Stefánia, or children's hospital, was inspected, as also the isolation pavilion for infectious cases. The members of the Congress now went on board a steamer and proceeded to the St. Marguérite Island, which is the great pleasure resort of the inhabitants of Buda-Pesth. Here, among trees and flowers, the municipality had prepared a splendid dinner-lunch. A band was in attendance, which played the national hymns of the principal nationalities present, and was answered by cheers from the different representatives. The ladies received presents of flowers and the gentlemen bunches of cigars and cigarettes tied up with ribbons in the colours of Buda-Pesth. Each delegate had also a decoration for his button-hole, bearing the arms of Hungary and the colours of Buda-Pesth, which proved of considerable practical service, as all the members of the Congress were at once recognised by the drivers of the carriages, tramcars, or the guards of the railways specially retained for the use of the Congress; everyone in the town was ready to help or guide those who wore this emblem.

The speeches were of a thoroughly international character. The Prefect, M. Charles Rath, in his opening allocution of welcome, declared that the town of Buda-Pesth would make the greatest efforts to forward scientific progress, and to carry out the wise counsel given by the Congress. M. Kamermayer, the Mayor, drank to Herren Ludvigh, the acting President of the Congress. Speeches now followed in rapid succession, but the allocution delivered by M. Sasvári was the most striking illustration of internationalism. He commenced in Magyar, and, after a few complimentary words to his Hungarian colleagues, assured the Austrian and German guests—himself speaking in good German—that the Hungarians recognised how much their civilisation was due to the Germanic races. Then, speaking in French, he explained that Hungary admired the great French nation, which, marching in the vanguard of progress, had given to the world the highest and most generous ideas. Now, changing from French to Italian, he spoke of the glories of ancient Rome, to be revived at no distant date. Finally, concluding in fluent English, he greeted the brave children of Great Britain, who had borne the banner of civilisation to the uttermost regions of the globe. Here the speech seemed ended, but, recognising among the delegates the dignified features and high turban of the Mahomedan Burgomaster of Serajevo, he again rose, and, in the Servian-Croatian language, hailed the presence of this Oriental functionary as typifying the union of the East and the West for the furtherance of the cause of hygiene. Dr. Roth, in Magyar, and Mr. Adolphe Smith, in French, spoke for England.

In the afternoon the Congress visited the new hospital, consisting of seventeen pavilions and holding 720 beds, and the model slaughterhouse for the town of Pesth. At the latter establishment 236,000 head of cattle are killed during the course of the year. It should be noted, however, that the consumption of poultry is nearly as large as that of ordinary meat.

In spite of these admirable institutions and the magnificent broad thoroughfares, the death-rate of Puda-Pesth is exceptionally high; it amounts to 29 per 1000. This, it is said, is in a great measure due to the fact that 25,000 people still live in cellars. The police have made vain efforts to drive the people out of these unwholesome abodes. The underground dwellings have one advantage, that of being cooler in summer and warmer in winter. The town drains directly into sewers, and these have their outfall into the Danube. The supply of drinking water is taken from the Danube. In spite of the great size of this river and the filtering process to which the water is subjected, this cannot be considered satisfactory, and probably also contributes to the high death-rate.

During the evening the greater part of the members of the Congress went to the opera, which is a model of comfort. There is no crowding, and even in the cheapest places the seats are as large and easy of access as the stalls of an ordinary London theatre. The ventilation was therefore much easier to maintain.

On the following morning the members of the Congress had again to bestir themselves early. The common rendezvous was for 8 o'clock, and a special steamer took us over to Buda to examine the magnificent Turkish baths, the Rudas-Fürdo, for which the town is justly celebrated. We then proceeded again by steamer to Promontor, formerly a Roman settlement, and where the vast caves of Mr. Saxlehner are cut out of the chalk formation several hundred yards deep into a mountain. In this weird place, beautifully illuminated by candles, a luncheon was served on barrels of wine. Caviare, or *pâté de foie gras*, and the excellent wines of the country were consumed with a recklessness that was perhaps not in keeping with the laws of hygiene, but which was the best response to so hearty a reception. On leaving these caves, innumerable carriages were in waiting to convey the members of the Congress over vine-clad hills to the spot where, from seventy wells, the celebrated Hunyadi János waters are collected. This vast establishment was carefully inspected. The waters are mixed so as to maintain them always at the same degree of strength. This is done in two reservoirs holding altogether 100,000 litres. From these the bottle-filling machines are supplied. These receive from each side a tray loaded with twenty-five bottles. In a moment the water drops into the bottles without any being spilt. These waters were discovered in 1863, but it was not till they were analysed by Baron Liebig that they acquired the wide reputation they now enjoy. The waters were then named after the Hungarian patriot, Hunyadi János, who in the fifteenth century defeated the Turks, and whose son Matthias was elected King of Hungary out of gratitude for his father's services. Some persons have stated that the name was meant to describe the waters; it simply recalls a hero whose memory is dear to all Hungarians. The works once examined, some 700 persons sat down to a most magnificent feast, while one of the best Austrian military bands played outside the dining pavilion. After a few words of welcome from M. Saxlehner, the proprietor of the waters, Professor Ludwig, President of the Congress, returned thanks for the hospitality received, and acknowledged the importance of the establishment. M. Jarchow explained that it had always been the proprietor's wish to have an opportunity, such as had now fortunately presented itself, of showing to so many members of the medical profession that no effort would be wanting on his part to warmly acknowledge the support he had received at their hands. Professor Schmidt, in proposing "The Ladies," made a happy reference to the fact that the springs had been discovered by a lady. Dr. Busback, the member for Buda-Pesth in the Hungarian Parliament, Professor Acglave for France, Professor Corradi for Italy, also spoke; and Professor Frankland, who, as one of our best authorities on water, had visited the springs with much interest, responded in the name of England. He said every effort would be made to give the Congress a worthy reception when it met in London; but, in acknowledging the proverbial hospitality of Hungary, he was obliged to confess they would not surpass in England the entertainment they had received that day.

It was now soon time to start again, for the vast establishments of the Red Cross Society at Buda had to be seen. Here the Congress was received by Dr. Emerich Ivanka, the director, and the lady patroness, Countess Livia Zichy, and Madame Bischitz. There are altogether twenty-three buildings belonging to the Buda-Pesth branch of the Red Cross Society. In the event of a war, there would be room for 800 wounded on these premises. Now they contain, among other things, 180 ambulance waggons, including some that served in the recent Servian war. Also there are 200 beds, packed and ready to be loaded on 32 waggons, with all the medical, surgical, and cooking appliances necessary, so as to establish at a moment's notice a hospital in any part of the country. The English delegates, and notably Dr. Mumby from Portsmouth, were much impressed by the preparedness of this establishment. Fears were expressed that in England we should not be so ready to meet an emergency. From this point some members of the Congress went to visit the lunatic asylum at Lipótmező, while others hastened to their hotel to dress for the banquet given that evening by the Hungarian Society of Hygiene. This was the third banquet given on one and the same day.

The Hungarian Society of Hygiene was only founded in October, 1886, and yet it already counts more than 2000 members. There are three sorts of membership: mere adherents, who pay one florin per year and have no right to vote; full members, who subscribe annually three florins; and life members, who pay fifty florins. The Society issues

Digitized by Google

a paper, the *Egészség*, which, being translated, means *Health*. There are 200 life members, and out of this number 105 were enrolled by the acting and active President, Dr. Markusovsfky. A few ladies also are members, and the Society gives lectures, distributes literature, brings pressure to bear with respect to vaccination, &c. The banquet they had provided was most elegantly served. It called forth many eloquent speeches, delivered in a great and perplexing variety of languages, and was followed by a ball that lasted until the small hours. Yet the next morning, a little after 8 o'clock, the members of the Congress had to meet at a far distant station, where, in a special train, they were conveyed to Moha, three hours' distance from Buda-Pesth. Here are situated the celebrated Agnes Springs, which provide a very pleasant sparkling dinner water. The heartiest welcome was extended to the members of the Congress, and a good dinner was, as usual, followed by many good and enthusiastic speeches. Mr. Charles Barshall, of the *Revue de l'Orient*, an influential paper published in French at Buda-Pesth, proposed "The Foreign Press," coupling THE LANCET with the toast. He insisted that science had been the father of freedom, and that the present Congress seemed to indicate it would become the parent of peace. The aristocracy of intellect, from thirty different nationalities, had worked in common at the Congress to secure the health and the happiness of mankind. Such harmonious international effort would not only benefit the cause of hygiene, it engendered the hope of general peace. Mr. Adolphe Smith replied for the foreign press, which had always sympathised with the struggles of Hungary. Hygienists loved free air and free water, plenty of both to secure cleanliness and health, whence sprang reason, and with reason knowledge and freedom, the basis on which science was founded. He therefore begged to return the compliment, and drink to the free press of Hungary. Dr. Frankland also spoke in very suitable terms, and when the banquet was over the girls employed in bottling the St. Agnes waters came forward, in their peculiar, neat, but simple dresses, and danced the various dances of the Hungarian peasantry. The greatest animation prevailed, and everyone joined heartily in the amusements of this rural fête till it was time to join the train and return to Buda-Pesth. Thus the Congress came to an end. That same evening and the next morning the members all left, and were scattered once more to all points of the compass. To everyone the memory of the hearty reception afforded will be cherished with feelings of pleasure and gratitude. Much has been learnt, and there was much to enjoy. But the best way of showing our high appreciation of what has been done at Vienna and at Buda-Pesth is to prepare at once for the organisation of the London Congress, so that it may at least be worthy of the precedent triumphantly established in Austro-Hungary.

BIRMINGHAM.

(From our own Correspondent.)

QUEEN'S COLLEGE.

THE council of this College has issued an advertisement announcing that they will at their next meeting proceed to the election of (1) a Professor of Gynæcology; (2) a Lecturer on Operative Surgery. This intimation is conveyed through the medium of a halfpenny evening paper, from which it may be inferred that the council has chosen a wide, if not a dignified, appeal to the masses. It is hardly likely that any response will be made from this source, since it is rumoured that there are candidates whose election is already assured, the routine of advertising being a very formal one.

MUNICIPAL ELECTIONS.

The medical element in citizenship does not hide its favours in this enlightened borough. The recent elections have been conducted in a spirited manner in several of the wards of the town, in one a local practitioner being returned by a large majority. In the administration of local affairs the appointment of medical men gives an important influence on the questions of sanitation and public health. There is always ample work to do, and if time can be found to do it, apart from the cares and responsibilities of practice, there is no reason why the duties of government should not be shared by the profession as well as by other callings.

TEMPERANCE QUESTIONS.

At a conference of the Midland Temperance League, attention was called to the evil effects of drinking at railway stations, and grocers' licences. An energetic protest was raised against the granting of these licences, it being stated that no Act of Parliament had done more to degrade and demoralise the women of the country than that which had granted to grocers power to sell intoxicating liquors. When Imperial politics have become a little more settled, there will probably be time to give more attention to domestic legislation. The subject bears strongly upon the well-being of the poorer classes, and all earnest reformers would be glad to see some amendment in the drinking propensities of the population.

HOSPITAL SUNDAY.

The amount collected on Hospital Sunday reached the sum of £3975 4*s.* 1*d.*, to be this year exclusively devoted to the Queen's Hospital. The highest total received during the twenty-eight years Hospital Sunday has been instituted was in 1878, when the figures stood at £6482.

Birmingham, Nov. 2nd.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

CLOSE OF THE NEWCASTLE EXHIBITION.

ON Saturday last, at night, after a most successful run, our Exhibition doors were closed, never to reopen. The total attendance was nearly one hundred thousand over two millions! while the attendance on Saturday was nearly fifty-five thousand. It is reported that the immense throng left the building with great reluctance, as if anxious to have yet another "look round." It is pleasant to say that this immense concourse, extending over so many months, were always perfectly well conducted, and also that the Exhibition has been a commercial success, paying its way and leaving a surplus, so that when the building is cleared from the "bleak Northumbrian moor," its site will awaken no unpleasant thoughts in the breasts of our many spirited guarantors. There was during last week a most interesting ambulance competition in the Exhibition gardens. The search parties were aided by electric light, and the different modes of assisting and bandaging &c. the wounded were illustrated. The first prize was awarded, and well deserved, by the 2nd Detachment of the South Shields Light Brigade. Dr. Mears of the Newcastle College of Medicine superintended, and organised the competition. At the Ambulance Hospital in the Exhibition grounds, 223 cases have been treated. The hospital was erected by Mr. R. Buckhall of London, and was lent for its purpose by that gentleman. None of the cases treated called for anything beyond minor surgery. The medical direction of the hospital was under Drs. H. Newton and W. C. and C. Wicks.

NEWCASTLE SUNDAY HOSPITAL FUND.

The usual collection was taken in the churches and chapels on Sunday last, and the workmen's contributions on the previous Saturday. The collections were taken under favourable auspices, fine weather prevailing. Boxes were also set up in the Exhibition on its closing day—a happy idea. It is too soon to say much about the comparative amount raised, but the indications are that it will be up to former years.

THE FEVER-STRICKEN VILLAGE.

Although several of the patients who are suffering from typhoid fever at Burnriggs, near Carlisle, are still seriously ill, their condition is not regarded as dangerous; the rest are gradually convalescing, and, as no fresh cases have occurred, it is hoped that the worst has passed, and that in the course of a little time the place may be relieved of the obnoxious title of the "fever-stricken village." The result, the papers say, has been chiefly due to the help which the indigent sufferers have received from the liberality of the public. The medical officers, Dr. Conway, the district medical officer, and Dr. Ross of Wetheral, have been unremitting in their attendance. In the matter of nursing also the Burnriggs patients have been most fortunate.

(From our own Correspondent.)

THE ROYAL MEDICAL SOCIETY.

THE 151st session of the Royal Medical Society was inaugurated last Friday evening by an address by Mr. John Duncan, F.R.C.S.Ed., senior surgeon to the Edinburgh Royal Infirmary. As a former president of the Society, it was natural that Mr. Duncan should be forcibly reminded of the advances that have taken place in medical science generally, and in the development of the Edinburgh school in particular, since his occupancy of the president's chair, a quarter of a century ago. In listening to his interesting and eloquent account of how the world has wagged these twenty-five years, the members of the Society (most of them students of the present *régime*) had abundant cause for satisfaction; for they heard of increased facilities offered them in their studies, of more commodious halls in hospital and school for their reception, and of an ever-widening field of scientific effort in which their life would be spent. In tracing recent advances in surgery, Mr. Duncan drew special attention to the remarkable manner in which the surgery of the body cavities has been developed; on the one hand by improved methods of exact diagnosis and treatment, and on the other by the application to surgery of deductions from the germ theory of fermentation. The changes thus effected have been nothing less than startling, and the future prospects of further advances are now singularly hopeful. In speaking more particularly of the Edinburgh School, and its methods of teaching, Mr. Duncan had many things to say, both good and evil. In comparing the student of to-day with his predecessor of twenty-five years ago, it was noticeable that he conformed much more closely to the type of the whole body of students than did his predecessor, who had much more individuality about his actions and his ideas. Still they could certainly say that now there were fewer of the purely sensual, of those who ate, drank, or slept too much, than was formerly the case. But the man who worked out of proportion, the bookworm, in more or less portentous form, had now become an established fact and a stern reality among them. Mr. Duncan then described in a few happily chosen sentences the types of students of the present day. The aptness and acuteness of his sketches elicited such applause and approbation from his large audience as showed they were well-drawn pictures, and not caricatures of the actual fact. Most valuable to all were his closing remarks, upon the proper proportionate relation of study and relaxation. On both points he can speak with peculiar appropriateness, for he might well claim a high position in both spheres, since his reputation as an athlete and a sportsman is no less well established by a large demonstration of practical results than is that of his position in the world of medical science by the valuable contributions he has afforded to modern surgery.

UNIVERSITY GENERAL COUNCIL.

The statutory half yearly meeting of graduates of the University took place last week, when matters of considerable interest were discussed with a good deal of animation by a very small meeting of the members of the Council. Such is the apathy which pervades this body that at this meeting there were barely thirty present, although there must be several hundred members resident in Edinburgh. The chief business of the meeting was the consideration of the report of the Business Committee on the subject of University Reform. That report detailed many measures of a liberating tendency as desirable features of the next Universities Bill; among them, increased representation of the graduates in the University Court; increased powers to be conferred on the Court as a governing body, in particular the administration of University funds, now solely carried on by the Senatus; and that the Council, and not the Senatus, should elect the representative of the University on the General Medical Council. On each of these recommendations in the report amendments were passed by members of the Senatus Academicus who attended the meeting, and in each case the amendment was negatived by a majority of but one or two votes. This result has been made the basis of a good deal of banter by the *Scotsman* newspaper, which delineates the typical Edinburgh professor as a hopeless anti-reformer and reactionary; and this in turn has led to the publication of two letters from Professor Kirkpatrick, the Secretary to the Senatus, enumerating ten far-reaching projects of reform in various parts of the University polity that have in late years emanated from members of the Senatorial body itself. This discussion, which has been transferred from an academic auditorium to the public arena of the daily press, will probably run the same course that many previous discussions of the same nature have followed: the professoriate will hear a good deal of plain speaking that may be worthy in some degree the careful consideration which it will doubtless receive; but whatever the force or the noise of these winds that may assail it, the University ship will proceed upon an unaltered course, for those who are at present at her helm prefer the canal route of safe precedent to the ocean voyage of Reform, with the dangers that may attend it. But those dangers must be some day faced and overcome if the University is to gain the ocean-haunting freedom and the ocean-like expansion which all her well-wishers desire for her in the future.

Edinburgh, Nov. 1st.

ABERDEEN.

(From our own Correspondent.)

THE UNIVERSITY GRADUATION OATH.

THE Senatus of the University, at a meeting held on Saturday, had before it the recommendation of the University Court in regard to the discontinuance of the graduation oath, and it was resolved to take the matter into consideration at a meeting to be held on Dec. 10th.

THE RECTORIAL ELECTION.

The election of Lord Rector takes place on the 12th inst. Three candidates, Lord Aberdeen, Mr. Goschen, and Mr. John Morley, were at first proposed; but Lord Aberdeen has withdrawn in favour of Mr. Morley as opposed to Mr. Goschen.

THE STUDENTS AND CLINICAL TEACHING.

A deputation from the fourth year's medical students waited upon the staff of the Hospital for Sick Children, to discuss the question of changing the visiting hour at that institution, so that the students might be able to attend both it and the Royal Infirmary for clinical instruction. It was agreed to change the hour from 11 A.M. to 1 P.M., and thus get over the difficulty mentioned in my last communication. At the Royal Infirmary both physicians and surgeons visited formerly at 12 o'clock, but by the new arrangement the former visit at 11 and the latter at 12 o'clock. This arrangement has the advantage of making it possible for the students to visit both medical and surgical wards each day. On the whole, therefore, the facilities for clinical work may now be considered satisfactory.

The Infirmary Jubilee Extension Fund now amounts to £25,813 16*s.* 6*d.*

DUBLIN.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

So far as the Apothecaries' Conjoint Scheme is concerned, only three Examiners will be elected by the College of Surgeons—viz., one in Physiology and two in Ophthalmic Surgery, the existing supplemental Examiners acting in the other subjects, such as Anatomy, Surgery, &c. The first examination for the diploma in Public Health will take place on December 5th and following days. The inaugural address at the opening of the Medical School of the College was delivered on Monday last by Sir William Stokes, Professor of Surgery in the College. The address is published in our present issue. At its conclusion a vote of thanks was moved to the lecturer for his able address, and passed with acclamation.

ROYAL UNIVERSITY OF IRELAND.

The conferring of degrees of this University took place last week, presided over by Lord Emly, the Vice-Chancellor, who, in the course of his address, said that one of the pleasant duties which from time to time fell to the lot

Digitized by Google

of bodies such as theirs was to bear public testimony to academic and professional merit existing in other places. They were about that day to enrol among their graduates men whose names were well known in the world of science, of letters, and of medicine. During the visit of the British Medical Association to Dublin last summer it was agreed that they should commemorate that event by conferring upon some few of the most distinguished members of the medical profession from the sister island their degrees in the different branches of the profession to which they belonged. The Senate had resolved to confer the honorary degrees of A.M. and D.Sc. upon Dr. Frederick McCoy, of the University of Melbourne. The honorary degree of Doctor of Medicine would be conferred upon Dr. Richard Quain, and the same degree (*in absentiâ*) on Dr. C. Bastian, Dr. Thomas Grainger Stewart, Professor of Medicine in the University of Edinburgh, and Physician to the Queen in Scotland; Sir Dyce Duckworth, representative on the General Medical Council of the Royal College of Physicians; and Dr. Matthews Duncan. The honorary degree of Master in Surgery would be conferred on Sir Joseph Lister, Mr. John Erichsen, Mr. John Marshall, Sir Thomas Crawford, Director-General of the Army Medical Department; and Mr. Thomas Bryant, surgeon to Guy's Hospital.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

The new buildings, which were commenced about two years since, may now be considered as completed, and were formally opened on Tuesday, the 1st inst., by the Rev. Dr. Haughton, F.R.S., who gave an introductory address. The new building has a frontage of some 120 ft., the northern part of the edifice being intended for the surgical department, and the southern for the chemical. The dissecting-room is 120 ft. long by 30 ft. wide; while in the surgical portion are three lecture theatres, to be used alternately by medical and surgical lecturers. There are also apartments for the registrar and the medical professors, preparation-rooms, and on the upper floor a special surgical museum 80 ft. by 32 ft. wide. The chemical lecture theatre can accommodate 400 students, and will be fitted with all the modern appliances for chemical demonstration &c. The cost of the new buildings has been about £14,000, and the sum, although a large one, will be regarded as very judiciously applied by all who take an interest in the success of the medical school of the University of Dublin.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

The fifth annual general meeting of the Academy of Medicine in Ireland was held on Oct. 28th, in the College of Physicians. It was moved and adopted unanimously that the title of the Academy be changed to that of the "Royal Academy of Medicine in Ireland." It was resolved to amalgamate the offices of general secretary and treasurer, and that the duties of both should be undertaken by the general secretary. Sir Charles Cameron proposed a motion to the effect that the bye-laws 59 and 60 should be so altered as to constitute the existing sub-sections, the chairman of each to be called the president, and the council to consist of six members only, which was adopted unanimously. The office bearers for the session having been appointed, the proceedings terminated.

Dr. Tate, late resident medical officer of the North Dublin Union, has been granted a superannuation allowance of £200 a year. He is suffering from paralysis.

Dublin, Nov. 1st.

BELFAST.

(*From our own Correspondent.*)

THE WATER SUPPLY OF BELFAST.

To those who have lived in Belfast, and who know the great amount of rain which usually falls there, it will seem strange that there should be any scarcity of water. However, the prolonged drought has been so continuous that the Water Commissioners have been obliged to restrict the supply from the reservoirs to four hours daily. Owing to this, considerable inconvenience has arisen at the barracks, the Royal Hospital, and at the workhouse. At the latter place it has been decided to open some wells which for a long time have not been in use; but as one of the guardians stated their situation was near that of an old cholera graveyard, it was decided, before using the water, to have it tested by the borough analyst. All over the north of Ireland there has been a great scarcity of water, and in some of the towns, as Lurgan, this has given rise to considerable inconvenience. During the past few days some rain has fallen, but not sufficient to make any perceptible change in the amount in the reservoirs.

THE LAGAN POLLUTION.

Some time ago, Dr Graham, a member of the medical profession, was returned as alderman for Cromac Ward on the sanitary question. There is to be an election to the Town Council this month, and the Lagan Pollution Committee have decided to run a number of candidates pledged to their programme. Dr. Graham has again been selected as a candidate for the aldermanship, and Dr. Henry Bingham is one of those chosen as a candidate for councillor. The programme of the Lagan Pollution Committee adopted at a recent meeting includes, among other points, the following:—(*a*) The effective and immediate sanitation of the town, with special reference to the purification of the River Lagan, and a thorough investigation of the main drainage scheme in all its incidents, including taxation &c. (*b*) That in view of having the best scheme for the drainage of the town, competitive plans be sought for, and a sum of money be devoted to the purpose from the corporate funds. (*c*) That no undertaking or Bill be promoted involving an expenditure of over £5000 of municipal money until a town meeting be held to consider and approve of the same in accordance with the custom prevailing in English boroughs. The gentlemen I have mentioned have, with others, been selected as candidates for Cromac Ward, the locality in which the Lagan flows. An influential deputation waited on the Town Council on Tuesday, with the view of learning what course the Corporation would propose to adopt, now that the joint reports of the Borough and Harbour Commissioners' engineers had been made. The deputation were listened to most courteously by the members of the Council, and subsequently the report in reference to the matter was read and adopted, from which I gather that it is recommended, with a view of carrying out an improvement of the Lagan so far as is within the Council's powers, if the consent of the Board of Trade can be obtained to the embanking of the ground opposite Ormean Park on the lines suggested by Mr. Salmond (engineer of the Harbour Board), which is estimated to cost about £7500, and if the Harbour Board will dredge the bed of the river, and place the excavated material on the ground to be reclaimed, the Council should contribute a reasonable amount towards the expense of wheeling and levelling the material, and should also complete the embankment. This would be an important part of the work recommended by the two engineers, and probably would lead to other owners of property along the river doing their portions.

NURSES FOR THE SICK POOR.

From a report recently issued by the efficient secretary of the Association for Nursing the Sick Poor, I learn that, through the kindness of a lady and her husband in Belfast, the committee have been able to employ an additional nurse in this most admirable work. There are now nine nurses in all, and through the kindness of the same friends the supply of water beds, air cushions, &c., has been renewed. The generous bequest left by the late Mr. James Lindsay to this Society has been paid over to the trustees; it amounts to £547 18*s.* 10*d.*, including interest.

THE CURE OF HYDROPHOBIA.

About ten days ago several children were attacked and bitten by a dog supposed to be suffering from rabies in the Shankhill district of Belfast. Through the kindness of the public a sum of money was raised, and they were taken to Mr. McGovern, who, it is said, has been very successful in curing, or rather preventing, this disease. His method is still a secret. The children have now returned to Belfast. Considerable interest is being taken in the matter.

ROYAL HOSPITAL.

The winter session was opened on Tuesday by an introductory address, delivered by Dr. Burden, pathologist to the hospital. After welcoming the students, Dr. Burden gave an interesting account of the morbid anatomy and pathology of the spinal cord. He then made some observations on the subject of inflammation, and concluded an

Digitized by Google

able address by exhorting the students to uphold and to continue in their future practice the traditions of the Belfast Medical School.

SMALL-POX EPIDEMIC IN LONDONDERRY.

I regret to learn that there has been an epidemic of small-pox in Derry. It would appear that during the past quarter of a year forty-two cases of small-pox were brought under the notice of the sanitary authority. Of these, twenty-one occurred in the District Lunatic Asylum, where there had been five deaths. Of the other twenty-one cases occurring throughout the city, there had been four deaths. A statement of the districts chiefly affected showed that the disease clustered largely in the vicinity of the City Infirmary. There had been two cases in the infirmary, both of which were convalescent. The majority of the other cases had been removed to the City Fever Hospital. Strenuous efforts had been made by the sanitary staff to stamp out the disease. All the medical men in the city were personally waited on by the executive sanitary officer, and requested to give prompt information of any cases of small-pox coming under their notice. A disinfecting chamber was erected at the Fever Hospital. Despite the epidemic of small-pox, it is most satisfactory to learn that the death-rate is 9·5 below the average of the sixteen principal towns in Ireland. It is stated that in all cases of small-pox where the patients had, by the advice of their medical attendants, gone to hospital recovery had ensued, most of the deaths having occurred in private houses.

Belfast, Nov. 1st.

FLORENCE.

(From a Correspondent.)

THE City of Flowers is filling rapidly, and by the close of the month the season will have begun with a brilliancy seldom surpassed in the Tuscan capital. Nothing can be more delightful than the atmosphere in which city and suburb are bathed. The perfection of autumnal weather tempts the most timid valetudinarian to San Miniato and Fiesole—the latter eminence basking in a sun which would be oppressive but for the snow-tipped Apennine, which acts as a refrigerator. Gray's noble outburst—

"O Fæsulæ, amœna
Frigoribus juga, nec nimium spirantibus auris,"

written, as it was, one summer a century and a half ago,—conveys a true description of the pleasure inspired by that lovely hill-resort in the October of 1887. The Arno, well-nigh a gravel-pit in summer, now rolls majestically seaward, strewn with the leaves of Vallombrosa, and heightening the charm of the afternoon drive or walk in the Cascine, on whose thinned foliage autumn has "laid a fiery finger."

The health of the city is satisfactory. No epidemic prevails within its precincts. Weeks ago there was an outbreak of small-pox; but it was strictly local, confined to the denizens of the Borgo di San Frediano, long notorious as in some respects the worst quarter of the city. Even there the cause was not far to seek. The Mercato Vecchio, or old market, in the Ghetto, has had for sanitary and social amelioration to be dismantled, and this was done without adequate provision being made for its unhoused inhabitants, who, accordingly, flocked across the river to the slums of San Frediano. There they were massed together in hovels already overcrowded and squalid, with every hygienic defect. Confluent variola soon declared itself, and filled the healthier quarters with such panic that multitudes of people, both native and foreign, have had themselves revaccinated. The epidemic has now disappeared, bequeathing to the Sanitary Giunta a further task in sedileship—that of knocking down the old city walls between the Porta Romana and the Porta San Frediano, so as to increase the breathing space and facilitate the circulation of the inhabitants.

The Florentine municipality has not been idle in improving the sanitary condition of the city. For years its water supply was not good—mostly drawn from *pozzi* or wells in the immediate neighbourhood of the houses. Most of these are still on tap, but they will ere long be closed, and replaced by the *acqua potabile*, already introduced into all the good houses and hotels. A memoir on "The Well Waters of Florence, and, in particular, on the Municipal Acqua Potabile," has just been published by Signor Napoleone Passerini, director of the School of Agriculture at Scandicci, in the neighbourhood. According to this authority, the *acqua potabile* does not, like that of many of the *pozzi*, contain pathogenic schizomycetes, but, compared with the latter, presents the following characters: 1. It contains a minute quantity of non-injurious organic matter, a quantity less than that of all the *pozzi* waters examined within the city, the *acqua potabile* yielding an average of 0·0633 gr. per litre, while that of the *pozzi* yields 0·334 gr. 2. The *acqua potabile* presents a smaller proportion of saline substances. 3. It is quite free from ammonia in solution, from azotised organic matter, and from nitrous acid. 4. The air dissolved in it possesses a greater proportion of oxygen than all the *pozzi* waters under examination, proving that the former has less organic matter on which oxygen can seize. 5. While, as already stated, it contains no pathogenic microbes, it presents all the characteristics of an excellent drinking water. On the other hand, the best of the *pozzi* waters cannot claim a higher place than that of a tolerable drinking water. The municipality, according to Signor Passerini, has only to persevere in its undertaking, and the water supply of Florence, whether as to quality or abundance, will leave nothing to be desired.

No medical or philanthropic visitor to Florence should omit to see a wonderful specimen of what education can do for the blind, in the case of Gaetano Baldelli, now exhibiting his powers at the Museo Internazionale dei Ciechi (International Museum of the Blind). We are familiar with those similarly afflicted who can read printed letters with their fingers; who, introduced into a room, can, by clapping their hands, tell us how large it is, and whether it contains furniture; who can cultivate flowers and distinguish them from weeds. But what must we say to a blind youth who can measure for clothes, cut them out, and make them up in the latest fashion? Baldelli does this before admiring crowds. In 1884 he received honourable mention at the Turin Exhibition held that year, and King Humbert graciously presented him with a gift, accompanied with expressions of praise and encouragement. In other cities throughout the peninsula, notably Milan, he has given specimens of the proficiency in the handicrafts to which the sightless may be educated; and, if his example is followed, Italy may ere long have a school for the blind not inferior to that of the nuns at Paris. These blind women can execute the most delicate and complicated embroidery, and can communicate to blind novices of their own sex the skill they so admirably exhibit. They can even teach those who can see how to do the most refined lace work. They can recognise the defects of these novices and correct them, breaking their work and remaking it; and all this intelligence and dexterity they show in other not less difficult operations of the milliner or the seamstress. It is believed that the peculiarly spiritual life these good women lead quickens and perfects all the other organs of special sense, and replaces that of vision by something almost like a substitute. But this is a question for accomplished medico-psychologists like Dr. Russell Reynolds, whose address on "Preventive Medicine," published in THE LANCET of October 1st, has, I may mention, been read with much admiration by more than one eminent Italian physician.

Oct. 22nd.

PARIS.

(From our Paris Correspondent.)

THE FACULTY OF MEDICINE.

THE winter session of the Paris Faculty of Medicine will begin on Thursday the 3rd inst., and the following is a list of the lecturers for the Session;—Medical Physics, Prof. Gabriel; Medical Pathology, Prof. Dieulafoy; Medical Chemistry, Prof. Gautier; Surgical Pathology, Prof. Lannelongue; Operative Surgery, Prof. Duplay; Histology, Prof. Duval; Morbid Anatomy, Prof. Cornil; History of Medicine and Surgery, Prof. Labouibène; Medical Jurisprudence, Prof. Brouardel. Clinical Medicine: Prof. G. Sée, at Hôtel Dieu; Prof. Potain, at La Charité; Prof. Jaccoud, at La Pitié; Prof. Peter, at Necker Hospital. Clinical Surgery: Prof. Richet, at Hôtel Dieu; Prof. Verneuil, at La Pitié; Prof. Trélat, at La Charité; Prof. Le Fort, at Necker Hospital. Mental Pathology and Diseases of the Brain: Prof. Ball, at Sainte-Anne Asylum. Diseases of Children:

Digitized by Google

Prof. Grancher. Syphilitic and Cutaneous Maladies: Prof. Fournier, at St. Louis Hospital. Diseases of the Nervous System: Prof. Charcot, at Salpêtrière Asylum. Ophthalmology: Prof. Panas, at Hôtel Dieu. Obstetrics: Prof. Du Budin, at the Clinical Hospital.

CREMATION.

In anticipation of the official opening of the Crematory which has been erected in the Cemetery of Père Lachaise, two experiments have been performed in one of the furnaces with the bodies of two persons who died in the hospitals unclaimed by their relatives. The bodies were incinerated in the presence of M. Chassaing, Vice-President of the Municipal Council of Paris, accompanied by other functionaries, the process occupying two hours, and each corpse produced 4 kilogrammes of ashes. Other experiments are to be performed during the week. The Crematory is situated in the north of the cemetery. It has the shape of a parallelogram and is three storeys high, surmounted by two chimneys in white stone. In a report drawn up by Dr. Brouardel, he estimates that the furnaces will be able to consume 4,500 bodies annually, which is about the average number taken from the Paris hospitals each year. The Bill authorising cremation in this country has been passed by the Chamber of Deputies, and it only remains for the sanction of the Senate. Meanwhile inhumation or incineration will be optional; but several generations will probably have to pass before cremation will completely replace inhumation, as, whatever may be the feelings of the French for their fellow-creatures during life, they have great respect for the dead, amounting almost to veneration.

"TANACETIC RABIES."

In continuing his researches on "tanacetic rabies," M. Peyraud read a paper before the Academy of Sciences last week on the preventive action of the hydrate of chloral on this artificial malady and true rabies. He instituted two series of experiments on rabbits and birds by intravenous injections with the essence of tanaisia followed by the subcutaneous injections of chloral. In the first case, after having produced the specific symptoms, he endeavoured to arrest their development by the subcutaneous injections of chloral, and it was thus remarked that when the tanacetic convulsions were established, the arrest of the malady did not take place. If, on the contrary, the animals were previously subjected to the action of chloral, and when they fell asleep or were simply drowsy and a certain dose of the essence of tanaisia was administered, the convulsive effects were not produced, or were produced tardily, and after repeated doses of this essence, when the quantity of chloral was insufficient. From this result the author concludes that if the chloral had not a *curative* action on tanacetic rabies, it evidently had a *preventive* action. The discoveries of M. Pasteur on experimental rabies gave M. Peyraud the idea of studying the two kinds of rabies comparatively, and his experiments led to the following results:—"On the 6th of March, 1887, I inoculated a large black rabbit by the submeningeal method, the rabic virus being taken from a man named Berger, who died six months after the Pasteurian vaccination, of paralytic rabies in Dr. Pitres' ward. This virus was of the third series of inoculation of rabbits. The paralytic rabies of the preceding series always reached the fifteenth day. Six others (*témoins*) were at the same time inoculated with the same virus. All six died from paralytic rabies six months ago, but the black rabbit is still living. It manifested only a slight weakness about the sixteenth day of the inoculation. The rabbit was treated in the following manner:—On the 10th, 11th, and 12th March it was placed under a bell-glass, and subjected during two hours and a half to the action of the fumes of chloral without its falling asleep. On the 13th, 14th, 15th, 16th, 17th, 18th, and 19th March the animal was injected subcutaneously with 10, 20, and 30 centigrammes of a solution of chloral (2 grammes to 250 grammes of water). The treatment lasted ten days, since which time it has not presented any morbid phenomenon, and it is probable that it will not become rabid, as it is now more than seven months since it was inoculated."

MONUMENT TO BRETONNEAU, TROUSSEAU, AND VELPEAU.

On Oct. 30th the monument erected to the memory of Bretonneau, Trousseau, and Velpeau was inaugurated at Tours, the birthplace of these eminent members of the profession. The ceremony took place in the presence of the officials of the town and of that of several members of the Faculty of Paris and of the neighbouring district. Among those present may be named Dr. Louis Thomas, Professor of Clinical Surgery, who presided, Drs. Duclos of Tours, Peter, Verneuil, Brouardel, Léon Labbé, Dieulafoy, Emile Vidal, Constantin Paul, Guyon of Paris, and pupils of these eminent professors. There were also present Dr. Hubert Trousseau, grandson of the celebrated physician, and Dr. Richet, son of the well-known surgeon of that name, who represented his father, as the latter was unable to attend.

Dom Pedro, the Emperor of Brazil, recently attended a meeting of the Biological Society of Paris, at which Professor Brown-Séquard, President, proposed his Majesty for the membership of the Society, and he was unanimously elected.

Paris, Nov. 1st.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: MEETING OF FELLOWS AND MEMBERS.

THE annual meeting of the Fellows and Members of this College was held yesterday (Thursday), under the presidency of Mr. Savory. After a brief statement from the President in reference to the extension and improvement of the College rooms, museum, and library, Mr. T. Holmes proposed, and Dr. R. Gooding seconded the resolution, which will be found quoted on page 920 of our present impression. This was carried unanimously. In speaking to the motion, Mr. Holmes said it was of a rather portentous length, but if ever laid before the Privy Council it would better tell its own tale. The case, he said, stands thus: There are about 1000 Fellows and about 12,000 Members of the College. It was felt to be curious that, with the exception of some twenty-four members of Council, the remainder of this large body corporate should be entirely excluded from all participation in College management; that this small Council should exercise absolute and uncontrollable ownership of the vast influence and wealth of the College of Surgeons. He reminded the Council that, even if the immediate struggle terminated in favour of the Council, it would not be given up, for there were still Parliament and the public to appeal to. He trusted, however, that when the matters in dispute had been submitted to an independent authority, such as the Privy Council, they might not unfairly expect a favourable answer.

On the motion of Mr. John Tweedy, seconded by Dr. Danford Thomas, it was unanimously resolved to respectfully request the Council of the College to transmit a copy of the foregoing resolution to the Lord President of the Council. Mr. Tweedy said he would have been glad to have had their differences settled in that room, but he could not be surprised at the opposition of the Council, and was certainly not disheartened. He recognised the right of the Council to hold to their own opinion; but still he thought, as this was a properly constituted general meeting of the College, which every Fellow and Member was entitled to attend, it was only right and proper and dignified that the Privy Council should be put into possession of the opinion of the meeting; the differences between the Council and the general body of the College were honest, and he for one was perfectly ready to fight them out.

After some discussion on points of order, which the President disposed of, the meeting terminated with a vote of thanks to the President for his courtesy and tact in the chair.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY. The first meeting of the third session of this Society took place on Oct. 26th, in the Faculty Hall, St. Vincent-street. The following gentlemen were appointed office-bearers:—Hon. President: Professor Leishman. President: Abraham Wallace, M.D. Vice-Presidents: J. Stuart Nairne, F.F.P.S.G.; Murdoch Cameron, M.D. Treasurer: Robt. Pollock, M.D. Reporting Secretary: Robert Park, M.D. Secretary: George A. Turner, M.D. Pathological Registrar: Nigel Stark M.B., C.M. Council: J. Marshall, L.R.C.P.E. (Coatbridge); John Glaister, M.D.; W. L. Reid, M.D.; P. C. Smith, M.D. (Motherwell); David Tindall, M.D.; and Skene Keith, F.R.C.S.E. An interesting and learned paper was afterwards read by Dr. Oliphant on the History of Pessaries.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were duly admitted Licentiates of the College on the 27th ult. The name of the medical school is appended in each case:—

*John Hill Abram, Liverpool; Thomas Wilson Aird, London; Henry C. Leffler Arnim, Charing-cross; *Walter J. Bearblock, Guy's; A. Babington Blackie, St. Thomas's; James H. Blomfield, University College; *Daniel Booth, Manchester; C. Carter Braine, Charing-cross; W. H. Breffitt Brook, St. Bartholomew's; *Edgar Browning, St. George's; T. W. Barnett Burn, St. Bartholomew's; *Ferberd R. Buswell, Middlesex; *Harry Johnston Campbell, Guy's; Adolphus Leo Castel, University College; *Samuel John Cole, London; *Beaumont Harry Comerford, St. Georges; R. James Cook, Guy's; Richard Cordiner, London; Percy Vernon Dodd and Arthur Reed Down, St. Bartholomew's; Herbert Edgelow and W. E. Evans, St. George's; *Frank Fawssett, St. Thomas's; *Walter Fisher, Guy's; *Frank E. Gibbens, W. Douglas Gimson, and Nathaniel J. Goodchild, St. Bartholomew's; Charles Greene, Birmingham; W. A. Griffiths, Westminster; F. W. Halliday, Leeds; *Percy Herbert Vickers Hammersly, St. Bartholomew's; Worsley John Harris and W. H. Hillyer, St. Thomas's; Christopher Whewell Hogarth, Guy's; Lionel Norton Hoysted, Charing-cross; C. H. Janes, St. Thomas's; *Ooram Llewelly Stuart James, J. James, and *J. H. B. Jarvis, London; *Frank Lane, London; C. Mortimer Lewis, St. Thomas's; H. W. Lewis, Guy's; Edwin Mellor Light, St. Georges; Charles Armstrong Lumley, Guy's; J. Black M'Ilroy, Westminster; Reginald Martyn, St. Bartholomew's; *Harry Forbes Churton Marvin, University College; C. E. Matthews, St. Thomas's; *W. Mortimer, London; *Berkeley George Andrew Moynihan, Leeds; Charles Pye Oliver, Charing-cross; Frank Pearce, Guy's; *Jeremiah Penny, King's College; G. A. Pratt, University College; *Richard Fairfax Reading, Middlesex; Harvey Rhodes, Manchester; Alex. Bruce Roxburgh, London; David Naunton Ruck, St. Bartholomew's; Bhagat Ram Sawhny, Lahore; *Prideaux George Selby, St. Bartholomew's; Harold Sidebotham, Manchester; B. O'Reilly Somers, Manchester; Matthew Henry Spence, St. Thomas's; W. H. Stevens and *Theodore Mayo Stiles, Bristol; Albert Max Sully, University College; *Shigemichi Suzuki, St. Thomas's; Horace Lawton Swete, London; Edgar Swindells, Manchester; Richard Francis Thomas, Middlesex; *Walter Thompson, Leeds; Robert Straker Turton, St. Georges; *W. H. Vickery, Middlesex; A. H. Ward, St. Georges; Frank Augustus Watkins, *John Houghton White, and Herbert Edmund Winter, St. Bartholomew's; Onslow Arthur Wickham, London; Sidney Wigglesworth, Manchester; *Richard Gerald Wilde, Cambridge and London; Bernard Duncan Zorapore Wright, St. Bartholomew's; Edmund Hasell Wright, St Thomas's; and E. T. Wynne.

* Approved by Examining Board.

ROYAL UNIVERSITY OF IRELAND.—The following degrees were conferred last week by Lord Emly, Vice-Chancellor of the University:—

BACHELOR IN MEDICINE.—Upper Pass.—John Campbell, Robert J. Duffin, W. M. Elliott, Gerald Hickey, John J. Lynch, Richard C. Mc Cullagh, Robert Nelson, W. J. O'Meara. Pass.—J. F. Annesley, Robert Bryans, David Campbell, James Clifford, Edward R. Crofton, Francis E. Gahagan, George R. Gordon, Walter Hamilton, William Killen, John McElwee, Peter McKenna, Samuel Mathews, Cecil Shaw, James Tomb.

MASTER IN SURGERY.—Honours, First Class and Special Prize of £20, Joseph Stewart. Second Class, John McIlwee, Robert J. Ferguson. Pass.—Robert Bryans, David C. Campbell, John Campbell, Robert J. Duffin, W. M. Elliott, John Ellison, Walter M. Hamilton, Gerald Hickey, W. M. Killen, W. M. Lewis, Hugh A. Logan, Richard C. Mc Cullagh, Henry Makisack, Samuel Mathews, Robert Nelson, D. J. O'Mahony, W. J. O'Meara, Francis L. Sealy, John H. Sharpe, Cecil E. Shaw, John J. Shaw, Henry J. Taylor, James Tomb.

MASTER OF OBSTETRICS.—David C. Campbell, John Campbell, W. M. Elliott, Robert J. Ferguson, W. M. Killen, Richard McCullagh, Henry L. Mackisack, Robert Nelson, Joseph Stewart.

The following exhibitions have been awarded:—

FIRST EXAMINATION IN MEDICINE.—First Class: Matthew Ledwith, £30. Second Class: Thomas Donovan, £15.

SECOND EXAMINATION IN MEDICINE.—Second Class: John Hennessy, £20; Thomas McDermott, £20; John Macnamara, £20.

M.B. DEGREE EXAMINATION.—Second Class, £25 each: Henry L. Mackisack, and Joseph Stewart.

SOCIETY OF APOTHECARIES.—The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling to practise as Licentiates of the Society on Oct. 20th:—

Beaver, R. Atwood, Alexandra-rd., Waterloo, Liverpool.
Bell, W. Whitmarsh, Fentiman-road, Clapham.
Chaud, Fateh, Assist. Surg., Indian Service, Punjab, India.
Cheatle, G. Leuthal, Vereker-road, West Kensington.
Richard Watson Councell, Victoria-road, Clevedon.
Gilchrist, T. Caspar, Victoria-street, Crewe, Cheshire.
Leicester, Morton Edmund, Chambres-road, Southport.
Marsh, A. Herbert, Manchester-road, Bolton, Lancs.
Parsons, G. Gooden, Middleborough House, Coventry.
Stocks, W. Percy, The Crescent, Salford.

The following gentlemen passed the Surgical portion of the examination during the month of October:—

Abbott, Frederic W., Charing-cross Hospital.
Beaver, R. Atwood, Liverpool School of Medicine.
Bokenham, T. Jessopp, St. Bartholomew's Hospital.
Carter, Ernest, London Hospital.
Clarke, Thomas Henry, Middlesex Hospital.
Coryn, Herbert A. W., Charing-cross Hospital.
Killick, Charles Rowe, London Hospital.
Leicester, Morton Edmund, St. Bartholomew's Hospital.

The following gentleman passed the examination in Medicine only on Oct. 20:—

Spong, Harry, Leeds School of Medicine.

The following candidates passed the examination qualifying them to act as Assistants in Compounding and Dispensing Medicines:—

Aukland, W. Henry.
Colman, William.
Downes, W. Francis.
Evans, Frederic Ernest.
Knott, Percy.
Matthews, John George.
Parish, Alfred James.
Price, Thomas Harry.
Thorne, Henry Courtenay.

APOTHECARIES HALL OF IRELAND.—At a special examination held on Oct. 26th and 27th, the the following received the Licence of the Hall:—

Alexander Stewart.

THE Hospital Sunday collections were made at Brighton and Plymouth on the 30th ult.

A WELL-ATTENDED meeting was held on the 29th ult. at the Mansion House, York, in furtherance of the objects of the Church of England Burial Reform Association.

VICTORIA HOSPITAL FOR SICK CHILDREN.—Arrangements have been going on for some time past to inaugurate a grand fête and festival in aid of the funds of this charity.

AN INTERNATIONAL FIRE, WATER, AND BURGLAR PROOF EXHIBITION is announced to be held in London, early in 1888.

NATIONAL DENTAL HOSPITAL AND COLLEGE.—Mr. Charles S. Tomes will preside at the Annual Students' Dinner on Friday, Nov. 25th, at the Holborn Restaurant.

THE annual dinner of the Glasgow Southern Medical Society was held on the 27th ult., Dr. M'Millan, President of the Society, occupying the chair.

THE annual meeting of the supporters of the Manchester Southern Hospital and Manchester Maternity Hospital was held on the 27th ult., when satisfactory reports were presented and adopted.

AT a public meeting held at Glasgow on the 24th ult. resolutions supporting the proposal to erect a new infirmary to commemorate the Jubilee were unanimously adopted.

THE Committee of the Jubilee Fund now being raised in aid of the Great Northern Central Hospital, in the course of erection in Holloway-road, report the receipt up to the present time of nearly £4000.

SUNDAY LECTURE SOCIETY.—On Nov. 6th Dr. Percy F. Frankland, B.Sc., will lecture at St. George's Hall on "Micro-organisms; their place in Nature, and how to study them," illustrated by diagrams and preparations.

THE inquest upon Hannah and Edward Bowles, who are alleged to have been poisoned at Camberley, has been adjourned for another fortnight. The authorities are very reticent as to the results already obtained from their inquiries.

FATAL FOOTBALL ACCIDENT.—At an inquest held on the 2nd inst. at Princes End, near Sedgley, on the body of a youth who received fatal injuries whilst playing football on the 29th ult., the jury returned a verdict of "Accidental death."

LITERARY ANNOUNCEMENTS.—A translation of Sir Morell Mackenzie's book on the "Hygiene of the Vocal Organs" has just appeared in Germany, from the pen of the well-known laryngologist, Dr. Michael of Hamburg, under the title of "Singing and Speaking." A Dutch translation of the same work, by Dr. G. D. Cohen Tervaert, of the Hague, will shortly appear.—The publishers of *Brain* announce that, owing to the serious and prolonged illness of Dr. A. D. Watteville, it will be impossible to publish Part 39 of that work in October. It has accordingly been decided that instead of publishing Part 39 very much after its proper date, it will be best to issue Parts 39 and 40 together in January, 1888.

Digitized by Google

A MEETING of the Association of Municipal and Sanitary Engineers and Surveyors for the Home Counties District was held at Luton on the 29th ult., chiefly for the purpose of inspecting the new sewerage works which were recently completed by the Corporation at a cost of £20,000.

HEREDITY AND NURTURE. — A course of three lectures on the above subjects will, with the permission of the Lords of the Committee of Council on Education, be given at the South Kensington Museum, on behalf of the Anthropological Institute, by Francis Galton, F.R.S., President of the Institute. The lectures will be delivered on Nov. 12th and the two following Saturdays, at 4.30 P.M.

AT the annual meeting of the Governors of the Doncaster Infirmary on the 27th ult. it was reported that the expenditure for the past twelve months was nearly £120 more than that of the previous year. This excess was attributed to the late railway accident at Hexthorpe.

BRITISH HOME FOR INCURABLES.—An Anglo-Danish fête will take place in May next, for the purpose of celebrating the silver wedding of the Prince and Princess of Wales, by rebuilding this institution, a course which has been rendered necessary by the expiration of the lease of the present premises.

WEST KENT MEDICO-CHIRURGICAL SOCIETY. — The following gentlemen have been elected officers and Council for the session 1887-88: — President: J. Brindley James. Vice-Presidents: Peter Horrocks, M.D.; Thos. Moore, F.R.C.S. Council: G. H. Cable, M.R.C.S.; Ernest Clarke, M.D., B.S.; Peter Cooper, M.R.C.S.; W. Collingridge, M.D.; Alex. Forsyth, M.D.; Frederick Moon, M.B.; J. Poland, F.R.C.S. Treasurer: Prior Purvis, M.D. Secretary: H. W. Roberts, M.R.C.S. Librarian: Ernest Clarke, M.D.

A CENTENARIAN.—The death is reported from Constantinople of a man named Dimitrios Antippa at the extraordinary age of 115. The deceased was born at Kephalonia in 1772, and, though in his later years he settled down as a merchant in the Turkish capital, he had passed his earlier days in Paris during the Reign of Terror, having had among his personal friends Marat, Danton, and Robespierre. To the last M. Antippa retained his clearness of intellect.

THE COLLEGE OF STATE MEDICINE.—At a meeting of the council on Wednesday, Nov. 2nd, Sir Joseph Fayrer, K.C.S.I., chairman, the following gentlemen were elected Associates of the College: Francis John Allan, M.D., D.P.H. Camb.; Jas. Richardson Andrew Clark, D.P.H. Camb; Francis H. S. Murphy, M.D., D.S.S.R. Irel.; Robert Sloss Stewart, M.D., D.P.H. Camb.; Francis Harper Treherne, F.R.C.S., D.P.H. Camb.; Alfred H. Twining, D.P.H. Camb.; William Henry Weddell, D.P.H. Camb.; and George Edward Cartwright Wood, M.B., B.Sc. (Public Health) Edin.

"THE FOOD WHICH HAS LAIN IN THE OOZE OF THE THAMES."—On 11th October the steamship *Escurial* collided with the steamship *Georgian* at the top of Greenwich Reach, and received damage. Five thousand packages of currants were wetted with clean salt water only. These were examined by the medical officer of health of the Port of London on Oct. 25th (the day before they were exposed to public sale), and were then found to be perfectly good for food. They were wet but sound, tasting slightly salt only. They required only washing to be perfectly good. They were passed as fit for sale. During the month of October 2000 tins of meat, 54 cases of oranges, 38 barrels of lobster, and 277 tons of beef have been seized by the port medical officer, and destroyed as unfit for food.

TRAGICAL DEATH OF A FRENCH MILITARY SURGEON. A tragical event has just occurred at Lille. A young military surgeon, who had committed some offence, was incarcerated in a disciplinary cell, and, being afraid of the hours seeming long at night, smuggled in a candle, which was contrary of course to the regulations, and lay in bed reading. After a time he must have fallen asleep, with the candle burning. Early in the morning smoke was observed by the non-commissioned officer outside to be issuing from the door. An alarm was raised, and the room entered. The cell was full of smoke from the bedclothes, &c., which had been on fire; and the body of the deceased, who had apparently been first suffocated and then burned, was found lying on the ground.

ON the 27th ult. the Jarrow magistrates fined a man 2*s.* 6*d.* and costs for wilfully exposing his son, who was suffering from scarlet fever, without taking proper precautions to prevent the spread of the disease.

ST. JOHN AMBULANCE ASSOCIATION. — A public meeting was held on the 26 ult. at the Assembly Rooms, Wood Green, Mr. J. R. Fitt in the chair, to advocate the formation of a branch of the above Association. An inaugural address was delivered by Colonel Duncan, C.B., M.P., who pointed out the advantages of instruction in "first aid" to persons of all positions of life, and instanced many cases where such knowledge had been of the greatest value, urging those present not to delay in joining a movement so philanthropic and unselfish in its object. Several local medical men having spoken in support, a resolution to commence classes forthwith was carried unanimously.

THE ROYAL ACADEMY OF MEDICINE IN IRELAND.—The following office-bearers have been appointed for the ensuing year:—Medical Section: President—James Little. Council—M. A. Boyd, J. H. Benson, A. Foot, Samuel Gordon, T. W. Grimshaw, R. A. Hayes, Alex. N. Montgomery, J. W. Moore, C. Nixon, Conolly Norman. Surgical Section: President—Anthony H. Corley. Council—William Colles, C. Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

CAUSES OF BLINDNESS.

DR. SERGIEFF, of the Vlatski province of Russia, who has taken notes of the causes of blindness of 824 persons in his locality, 501 of whom were females, finds that the cause is trachoma or granular lids in 245 cases, disease of the cornea in 129, cataract in 110, small-pox in 112. Injuries accounted for less than 5 per cent. of the cases. Amongst 1176 persons blind of one eye, 222 referred the cause to injury, a large number of these stating that they had met with accidents with the straw during harvest time.

Messrs. Hothersall and Co.—We have no recollection of having made reference to the matter.
